ON

CHINESE MATERIA MEDICA.

BY

DANIEL HANBURY,

FELLOW OF THE LINNEAN AND CHEMICAL SOCIETIES OF LONDON, MEMBER OF THE IMPERIAL LEOPOLDINE-CAROLINE ACADEMY, CORRESPONDING MEMBER OF THE SOCIÉTÉS DE PHARMACIE OF PARIS, BRUSSELS, ETC.

Reprinted, with some corrections, from the Pharmaceutical Journal and Transactions.

LONDON:
PRINTED BY JOHN E. TAYLOR.
1862.
PREFACE.

As originally published, the following *Notes on Chinese Materia Medica* are scattered through the pages of two volumes of the 'Pharmaceutical Journal,' and therefore not conveniently accessible for reference. In the present pamphlet they are collected, paged continuously, and supplied with a title-page and index.

D. H.

*February, 1862.*
NOTES ON CHINESE MATERIA MEDICA.

BY DANIEL HANBURY, F.L.S.

To draw up a general description of Chinese Materia Medica is a task that in the present state of our knowledge of the natural history of China, it were almost vain to attempt. Opportunities for scientific investigations in that vast country have as yet been far too limited, its zoology, botany, and mineralogy too little explored to enable any one to describe other than in a very imperfect manner even a small number of the varied products derived from the animal, vegetable, and mineral kingdoms, which come under the general denomination of drugs. But although sources of information are scanty, they are not entirely wanting; and I have, consequently, been led to think that under the simple title of Notes, it might be both useful and interesting to place upon the pages of a scientific journal such remarks upon Chinese Materia Medica as have been suggested by the examination of a considerable number of specimens which I have received through the kindness of friends in China. That, therefore, which I propose to do in the following pages is to give a short descriptive catalogue, firstly, of some of the mineral substances employed in Chinese medicine, which I have had the opportunity of examining, and of most of which I possess specimens; and, secondly, of a small number of animal and vegetable products, which may, from their origin, uses, or affinities, be of interest to the pharmacologist. The imperfectness of the information I have collected will, I trust, induce further researches on the part of those who being residents in China have opportunities which I cannot command, but with whose labours I shall always be glad to co-operate.

Before commencing the task proposed, it is desirable briefly to review some sources of information upon Chinese Materia Medica, to which frequent reference will have to be made.

Of a considerable number of native works, the most important and well-known is, undoubtedly, the great herbal entitled Pun-tsao-kang-mik, written by Le-shé-chin, in the middle of the sixteenth century. It was commenced in the reign and by command of the Emperor Kea-tsing, and completed by the son of

* Like other Chinese names, it is written by Europeans in various manners, as, Pen theaokang mo, Pen tsao camg mou, &c.
the author in the reign of Wan-leih, to whom it was presented in the year 1596. For some centuries previous to this period, works of the same character had appeared at intervals, some of them published by authority of the government, and others by private individuals. Of a few of these works, Du Halde has preserved slight notices, to which I would refer the reader who is desirous of further information.* According to this author, the Pun- tsao of Le-she-chin was written with the design of obviating the difficulties and confusion arising from a multitude of authorities, by supplying in one work a compendium of all that was more valuable in its predecessors. This design it probably fulfils, as it is held in high estimation by the Chinese and is frequently reprinted; but, excepting a revision and enlargement which it underwent in the fourteenth year of the Emperor Shun-chi, A.D. 1657, no attempt appears to have been made for the verification of old, or the acquisition of new, information. The Pun- tsao is divided into 52 chapters, usually bound into about 40 thin octavo volumes, the first three of which contain woodcuts of many of the minerals, plants, and animals referred to in the text. These woodcuts, four of which occur on a page, amount in number to more than 1100: the name is placed above each, and sometimes a synonym at the side. No general translation of the Pun- tsao into any European language has been published, though small portions of the work to illustrate particular subjects have frequently been translated. These extracts show that among much that is interesting, there is a large admixture of the absurd and fabulous, so that it is questionable whether the labour of translating so voluminous a work in its integrity would be repaid by the value of the information acquired. It is much to be desired, however, that a list of the woodcuts should be drawn up and printed, together with the Latin names of such minerals, plants, or animals as can be identified: such a list would form a convenient key to the Pun- tsao, and although but a comparatively small number of the names might at first be determined, a basis would be laid for future labours.

To give some idea of the subjects treated in the Pun- tsao, and the manner in which they are arranged, I have drawn up the synoptical table of its contents printed on the opposite page, which Professor Stanislas Julien of Paris has favoured me by examining and correcting.† With regard to European works touching upon Chinese Materia Medica, the first to be mentioned is one entitled Specimen Medicinis Sinicae, published in 4to, at Frankfort, in 1682. This work, which was edited by Andrew Cleyer, a physician and botanist in the service of the Dutch East India Company, is a collection of Latin treatises, some of them being translations from the Chinese. A list of these treatises (not, however, agreeing with the titles of the treatises themselves) is placed on the title-page. The author or translator of most, if not of all, of these works, was not Cleyer, but Michael Boym, a Polish Jesuit missionary, who went to China and India in 1643. After Boym's death in 1656, his MSS. were sent to Europe, where those constituting the work in question were published in 1682. Owing, however, to disagreements between the Dutch East India Company and the Jesuit missionaries, the name of Boym was suppressed, and the work appeared as edited by Dr. Cleyer, first physician to the

* Description de l'Empire de la Chine, Paris, 1735, fol. Tome iii., p. 441.
† I may also here acknowledge the information I have derived from Du Halde (Op. cit. iii., 437-9), as well as from Mr. S. Wells Williams, in the comprehensive account of the Pun- tsao given in his Middle Kingdom, vol. i., chap. vi. I have also to thank my friends Messrs. Lockhart and W. G. Stronach, who have kindly determined for me many points involving a knowledge of the Chinese language.
SYNOPSIS OF THE CONTENTS OF THE CHINESE HERBAL

1. Introductory Observations upon the practice of Medicine and Index of Receipts.
2. Lists of Medicines for the cure of all Diseases.
3. Waters, Fires and Earths.

8. MINERAL... Metals
9. I. Stones
10. II. Stones [as Common Salt, Alum, Borax, Sulphur, &c.]
11. Saline Stones

13. VEGETABLE... 1st Division, HERBS
1. Hill Plants
2. Odoriferous Plants
3. Plants which grow in damp places
4. Poisonous Plants
5. Creeping and Climbing Plants
6. Aquatic Plants
7. Rock Plants
8. Mosses and Lichens

22. 2nd Division, GRAINS
1. Hemp, W. Rice, &c
2. Millet, Maize, &c
3. Leguminous Plants

26. 3rd Division, CULINARY HERBS
1. Plants having a strong odour and pungent taste [as garlic, mustard, ginger, &c.]
2. Soft and smooth plants [oyster, lettuce, chicory, mallow, &c.]
3. Plants producing fruit upon the ground [as the gourd tribe]
4. Aquatic Vegetables [as edible seaweeds]
5. Fungi
6. Cultivated Fruits
7. Hill Fruits
8. Foreign Fruits
9. Aromatic Fruits

34. 5th Division, TREES
1. Aromatic Trees
2. Stately Trees
3. Bushy Trees
4. Parasitic Plants
5. Flexible Plants and Trees [as osier, bamboo, &c.]
6. Miscellaneous Trees

38. On Garments and Domestic Utensils [pertaining to medicine.]
39. ANIMAL... 1st Division, INSECTS
1. Insects born from eggs
2. Insects produced by metamorphosis
3. Aquatic Insects [including frogs]
4. Dragons
5. Serpents
6. Fishes having scales
7. Fishes without scales
8. Birds living upon open lands
9. in woods
10. Mountain Birds
11. Domesticated Birds
12. Wild Animals
13. Rodent Animals
14. Monkeys

* This series of numbers does not exist in the original. When added in MS. it affords a convenient and ready means of reference to any particular figure.
Company. The treatises comprised in the *Specimen Medicinae Sinicae*, relate chiefly to medical subjects, and especially to the Chinese doctrine of the pulse. One section, however, of 90 pages, attributed to Boym, is entitled, *Medicamenta simplicia quae a Chinensibus ad usum medicum adhibentur*. It is an unclassified catalogue of 289 drugs, giving of each the Chinese name written after the Portuguese orthography, but without the Chinese characters; to this succeeds a brief description, chiefly as regards medicinal properties, which are expressed according to Chinese ideas. Occasionally the author is able to add the European name.

Incomparably more important and useful than Clever's *Specimen* is a little work published at St. Petersburg in 1856, for a copy of which I am indebted to the kindness of Professor Horaninow. It is entitled *Catalogus Medicamentorum Sinensium qua Pekini comparanda et determinanda curavit Alexander Tatarinov, Doctor Medicinae, Medicus Missionis Rossicae Pekinesis spatium annorum 1840—1850*. (Petropoli, 1856. 8vo.) It is, as its title implies, the catalogue of a collection of Chinese drugs obtained in Pekin by Dr. Tatarinov, physician to the Russian mission in that capital, which drugs, as we learn from the preface, were subsequently examined and for the most part determined by Dr. Paul Horaninow, professor of Materia Medica at St. Petersburg. With the exception of the title-page and preface, which are in type, the catalogue is in lithograph, and forms a thin octavo of 65 pages. The Chinese characters for each name are given, and their sound expressed both in Russian and English writing characters. The arrangement is alphabetical, according to the names written after the Russian orthography. The name of each drug, so far as it could be determined, is given in Latin without note or comment. The catalogue includes the names of 500 substances.

Although these two are the only European works with which I am acquainted, that professedly treat of Chinese Materia Medica, there are some other valuable sources of information, which are too well known to require more than the briefest notice; such are the *Flora Cochinchinensis* of Loureiro, a work in which the medicinal properties of many plants of Southern China are briefly noticed. The *Amenitates* of the German botanist Kämpfer, published in 1712, contains an important section of 145 pages upon Japanese plants, for many of which the Chinese characters with their Japanese sounds are given. Nor should I omit to mention an Index of Plants of Japan and China, published in 1852 by MM. Hoffmann and Schultes, in which the Latin names of about 600 species are enumerated, together with their equivalents in Japanese and Chinese, the Chinese characters being given.

With regard to inorganic Materia Medica, some information as to the Chinese designations of various mineral substances may be gathered from Keferstein's *Mineralogia Polyglotta* (Halle, 1849, 8vo, pp. 248); the Chinese words, however, are expressed only in Roman characters.

The mineral Materia Medica of the Chinese is such as one may expect to find among a people having no scientific acquaintance with chemistry. Numerous substances are employed which are devoid of all active medicinal properties, while others of great power are so administered that the dose must be extremely uncertain. Although most of their mineral drugs are used in the crude state, there are a few, such as the mercurials, which are the results of chemical operations that are evidently conducted with considerable skill.

In the following list I have thought it best to group the substances described under the simple headings of *Calcaneous, Magnesian, Arsenical, &c.*, instead of attempting any more scientific arrangement.

* *Journal Asiatique*, Oct., Nov., 1852.
SULPHUR.

倭硫黄 Wei-lew-hwang; Native Sulphur.—Kämpfer states that it is found abundantly in Japan.

硫黄 Lew-hwang; Sulphur.—Cleyer, Med. simpl., No. 157; Pun-tsaou, fig. 85. The specimen has been fused and partially crystallized; it has a greyish-yellow colour.

SILICA.

白石英 Pth-shth-ying; Massive Quartz.—Pun-tsaou, fig. 20.

ALKALINE SALTS.

硝 Seaou; Nitrate of Potash.—The Chinese distinguish several varieties, as Pó-seaou, Wang-seaou, Ma-ya-seaou, &c.

鹼 Keên; Native Carbonate of Soda.—Dr. T. Martius has described this substance, a quantity of which was imported into Hamburg in 1845. It is said to be found on the Thibetan frontiers of China.*

硼砂 Păng-sha; Borax; Biborate of Soda.—An excellent sample of refined borax: probably imported in a crude state into China from Thibet, where, as is well known, it occurs in certain lakes. Borax is extensively used in China by silversmiths and coppersmiths.

元明粉 Yuen-ming-fun; Sulphate of Soda.—It is in crystals, and obtained in all the northern and central provinces of China. M. Rehmann enumerates it in his catalogue of Thibetan medicines.†

硼砂 Naou-sha; Chloride of Sodium (a peculiar form).—The specimen which I have received under the above Chinese name is a small rounded fragment of a crystalline substance, of a greyish-green hue, which upon analysis proves to be nothing more than chloride of sodium contaminated with a little earthy matter. Such, however, it cannot be regarded by the Chinese, who from some fanciful idea, possibly derived from the locality whence it is obtained, imagine it possessed of great medicinal virtues, and pay for it at the extraordinary rate of 20 dollars (£5) the ounce.

Naou-sha is stated by Keferstein to be a name for carbonate of ammonia and sal-ammoniac, but I have received neither of these substances from China.

CALCAREOUS SUBSTANCES.

寒水石 Han-shuy-shíh; Calcareous Spar (Carbonate of Lime); Hán xiū xè, Cleyer, Med. simpl., No. 160.—It consists of fragments of colourless crystals.

光粉 Kwang-fun; Levigated White Marble (Carbonate of Lime).—This substance is sold in the form of cakes, each weighing from two to three ounces, and enclosed in a little box. It is a remarkably pure form of carbonate of lime, and a very good specimen of careful levigation.

鐘乳石 Chung-joó-shíh; Carbonate of Lime in stalactitic masses. —Pun-tsaou, fig. 37. It is obtained from caves. The Chinese name signifies Hanging— (like a bell) milk-stone.

† Bulletin de Pharm., t. iii., p. 392.
NOTES ON CHINESE MATERIA MEDICA.

Hua-luy-shih; a granular greenish-white Dolomite (Carbonate of Lime and Magnesia).

Heuen-tsing-shih; Selenite (Sulphate of Lime).—Pun-tsaou, fig. 80. Small lenticular crystals (sometimes twin-crystals), translucent, but having a dull exterior. They vary in diameter from \( \frac{1}{10} \) to \( \frac{1}{8} \) of an inch.

Shih-kaou; Fibrous Gypsum (Sulphate of Lime).—Xè cão, Cleyer, Med. simpl., No. 166; Pun-tsaou, fig. 27.

Tsze-shih-ying; Fluor Spar (Fluoride of Calcium).—Pun-tsaou, fig. 21. In fragments of irregular size, and of a purple or greenish colour.

Yang-khe-shih; Asbestous Tremolite; Silicate of Lime and Magnesia. Pun-tsaou, fig. 44.—Irregular masses of a pale greenish colour.

MAGNESIAN AND ALUMINOUS SUBSTANCES.

Yin-tsing-shih; Silvery-white Mica.—Pun-tsaou, fig. 54. I have also received a transparent green mica under the same name.

Kin-tsung-shih; Brown Mica.—Pun-tsaou, fig. 54.

Tsung-mung-shih.—Pun-tsaou, fig. 56.

Kin-mung-shih; Cĩm mūn xè, Cleyer, Med. simpl., No. 154.

Yin-mung-shih.—This substance, and the two preceding, are micaceous earths.

Kwei-hwō-shih; Steatite or Soapstone; Silicate of Magnesia.—Hwū-shih, Pun-tsaou, fig. 31. A friable, greyish-white variety:—the so-called Soapstone, from which the Chinese often carve beautiful ornaments, is a silicate of alumina, known to mineralogists as Agalmatolite.

Hung-sha.—This substance is in the form of coarse reddish-brown sand, which, when examined with a lens, is seen to consist of transparent angular fragments, mostly of a pale pinkish hue, mixed with some of a yellowish-brown, or more rarely greenish-black. Sp. gr. 3.848. Professor Guibourt considers it is probably some variety of garnet reduced to powder, and in the absence of positive information I have therefore placed it among the aluminous substances.

Fei-hwō-shih.—An argillaceous earth, of a pale yellowish colour, soft to the touch, and formed into little, rectangular, oblong blocks.

Chth-shih-che.—An aluminous earth, of a pale pinkish colour, or white, in soft, friable, irregular masses. It has been examined by Mr. J. Morland, jun., whose analysis shows its composition to be nearly that of Kaolin. The two are as follows:

<table>
<thead>
<tr>
<th>Chth-shih-che.</th>
<th>Pure Kaolin.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Silica...</td>
<td>42.93</td>
</tr>
<tr>
<td>Alumina ...</td>
<td>36.53</td>
</tr>
<tr>

<td>.94</td>
</tr>
<tr>
<td>Water ...</td>
<td>14.75</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td>100.0</td>
</tr>
</tbody>
</table>
The *Chih-shih-che* contains also a trace of fluorine, which was calculated with the oxides of iron and manganese.

白礬 *Pth-san*; Alum.—*Pun-tsaou*, fig. 86.

**Arsenical Substances.**

信石 *Sin-shih*; Arsenious acid, also called *Pth-sin* and *Hung-pe*.—Of the specimens which I have received, some are apparently a natural mineral, constituting a translucent, crystalline mass, varying in colour from pure white to a yellowish-brown or grey. Other specimens have the aspect of the ordinary massive white arsenic of European commerce.

雌黄 *Tsze-hwang*; Yellow Sulphuret of Arsenic; Native Orpiment; *Pun-tsaou*, fig. 26.—It occurs in the province of Yunnan; probably also in Burmah, as it has been shipped in considerable quantity from Moulmein. Aindie states that it is exported from China to India.*

Orpiment is resorted to by the Chinese in cases ofague, but compounded in a manner so absurd as to render the dose extremely uncertain or even a non-entity.

雄黄 *Heung-hwang*; Native Red Sulphuret of Arsenic; Realgar; *Hium hoam*, Cleyer, *Med. simp.*, No. 176.—It is found in the province of Yunnan, in the south of China, and has been exported in small quantity to London from Canton. Realgar is also sometimes imported into England from Bombay.

Small shallow cups, elegantly carved out of this mineral, and often highly polished, are used by the Chinese for administering certain medicines; by which means, when the inner surface of the cup is, as sometimes happens, in a somewhat disintegrated condition, it is evident that a minute dose of arsenic may be administered. One of these cups, with its fanciful wooden stand, is represented in the annexed woodcut. Other carvings, but of a purely ornamental nature, are also manufactured from realgar by the Chinese, and, from their magnificent red colour and fine polish, are often of considerable beauty.

紅信 *Hung-sin*; Red Sulphuret of Arsenic with Arsenious Acid.—A native mineral, constituting a highly crystalline, striated mass, of a red or pinkish colour, mottled with white,—passing in places into a steel grey. It is composed of Red Sulphuret of Arsenic with a large proportion of Arsenious Acid. The dark parts are probably due to metallic arsenic.

**Compounds of Zinc, Lead, and Copper.**

浮甘石 *Pow-kan-shih*, also called *Loo-kan-shih*; Zinc Bloom. Dana, *Syst. of Mineralogy*, Ed. 4, vol. ii., p. 460.—An opaque white mineral, easily

* Mat. Med. of Hindoostan, p. 58.
broken and marking the fingers like chalk. It consists chiefly of fragments of a botryoidal crust, showing, when broken, a glistening, fibrous, radiating structure, sometimes divided into bands or layers slightly stained with oxide of iron. Mr. J. D. Perrins, of Worcester, who has obligingly examined the mineral for me, found its specific gravity (taken with precautions to deprive it of the air in its pores) to be 2.67. Mr. Perrins's analysis gave its composition as follows:

<table>
<thead>
<tr>
<th>Component</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oxide of Zinc</td>
<td>72.64</td>
</tr>
<tr>
<td>Carbonic Acid</td>
<td>14.95</td>

</tr>
<tr>
<td>Carbonate of Lead</td>
<td>1.78</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>100.00</strong></td>
</tr>
</tbody>
</table>

From these results, which closely approximate to those obtained by Smithson from the analysis of a similar mineral from Bleiberg, in Carinthia, the following formula may be deduced: $\text{ZnO, CO}_2 + 2$ (ZnO, HO), with an admixture of PbO, CO$_2$. Zinc Bloom, according to Dana, occurs with ores of zinc and lead at Bleiberg and RaitEL in Carinthia, where it has probably resulted from the decomposition of calamine.

The Chinese mineral is from the southern province of Kwang-si. As found in the native drug-shops, it occurs chiefly in pieces of from one-quarter to one inch in length. Larger pieces, which are perfectly white, are worth 400 cash the tael, which equals about one shilling per ounce.

密陀僧 *Meth-to-sang*; Litharge (Oxide of Lead).—*Pun-tsaou*, fig. 8; Cleyer, *Med. simpl.*, No. 168.

韋丹 *Wei-tan*; Red Oxide of Lead; Red Lead.

東丹 *Tung-tan*; a dull red powder, consisting chiefly of Red Lead and Carbonate of Lime.

鉛粉 *Yuen-fun*; Carbonate of Lead; White Lead. Prepared at Canton and Soo-chow. A compound plaster, of which carbonate of lead and oil are the chief ingredients, is used by the Chinese.

銅綠 *Tung-lü*; Carbonate of Copper (artificial).—It occurs in the form of small rectangular cakes of a pale, green colour, opaque and friable.

**FERRUGINOUS SUBSTANCES.**

鹽生 *Yen-sàng*; Magnetic Oxide of Iron.—A coarse, black, sand-like powder, strongly attracted by the magnet.

靈磁石 *Lin-tsze-shih*; Magnetic Iron Ore.—*Pun-tsaou*, fig. 45.

自然銅 *Tsze-jen-tung*; Per-oxide of Iron in cubic masses more or less broken.—It appears to have been obtained by calcining iron pyrites. *Pun-tsaou*, fig. 5.

代赭石 *Tae-choo-shih*; Red Hæmatite; Per-oxide of Iron. *Pun-tsaou*, fig. 46. It has the form of botryoidal concretions, with a scaly fracture, and ferruginous, metallic appearance.

禹糧石 *Yu-leang-shih*; Brown Clay Iron Ore.—Nodular concretions.
resembling the *Lapis ætites* of old European Pharmacy, a mineral which, to use the words of Geiger, "*olim dementer ad partum promovendum adhibebatur*.”

無名異 *Woo-ming-e;* Hydrous Peroxide of Iron in rounded grains; Limonite.—*Fun-tsaou*, fig. 34. This substance consists of rounded grains, varying in size between coarse sand and mustard-seeds, with occasional grains still larger. Some of them have a dark, polished surface, and metallic appearance, but the majority are brown in colour, and are more or less dull, when pulverized their colour is ferruginous. They are not attracted by the magnet. An analysis by my friend Mr. J. Morland, Jun., shows them to have the following composition:

<table>
<thead>
<tr>

</tbody>
</table>

Dr. Ure mentions a pisiform variety of Brown Clay Iron Ore in small solid spherical grains, which is used in Dalmatia as shot. The Chinese mineral is found in the provinces of Szechuen and Kwangtung.

蛇含石 *Shay-han-shih;* Nodular Iron Pyrites, more or less passed into the condition of per-oxide.

砳礬 *Lii-fun;* Green Sulphate of Iron.—*Fun-tsaou*, fig. 87. It is in the state of coarse powder.

**MERCURIAL COMPOUNDS.**

水銀 *Shi-yin;* Mercury.—*Fun-tsaou*, fig. 24.

紅升薑 *Hung-shing-yô;* Nitric Oxide of Mercury; Red Precipitate.—A heavy powder, of an orange-red colour, leaving no appreciable residue upon being heated to redness. It contains a little nitrate of mercury, but no arsenic.

輕粉 *King-fun;* Chloride of Mercury; Calomel.—My specimen of the substance called *King-fun*, consists of small, brilliant, colourless, transparent crystals, mostly thin and plate-like, or even pectinated; some are needle-shaped. Chemical examination proves it to consist of two distinct substances, namely, Chloride of Mercury and Sulphate of Lime. The chloride is in a state of great purity and beautifully white. The sulphate of lime is in minute, transparent, acicular crystals, to the naked eye perfectly simulating the chloride of mercury, which it is ingeniously used to adulterate. The proportion in which the two salts exist, is not readily determined, as it is impossible to obtain a uniform mixture for experiment without powdering the entire specimen. From three experiments however, it appears that sulphate of lime constitutes at least a fourth part of the specimen of Chinese Calomel under notice.

*King-fun* is mentioned by Cleyer as *E kim fuen*, and supposed by him to be a natural production, a suggestion quite inadmissible as regards my specimen. Mr. Lockhart informs me it is brought from the province of Gan-hhwuy, but of the locality where it is manufactured, and of the process, I am quite ignorant. The Mongols are said to purchase *Sublimate* of the Russians: *—perhaps by this*

* Bull. de Pharm. iii., p. 387.
we may understand Calomel also. The Chinese appear to have a correct notion of the use of calomel as a purgative, and they also employ it in the form of ointment in cases of ulcer, to cleanse and produce a free purulent discharge.

砳砂 Choo-sha; 丹砂 Tan-sha; Cinnabar; Red Sulphuret of Mercury.—Pun-tsoou, fig. 23; Clever, Med. simpl., No. 177. This mineral has been regarded by the Chinese as the Philosopher’s Stone, and most extravagant ideas have been entertained respecting it. The Rev. J. Edkins in a communication recently laid before the China Branch of the Royal Asiatic Society* has pointed out that alchemy was pursued in China long previous to its being known in Europe,—in fact, that for two centuries prior to the Christian era, and for four or more subsequent, the transmutation of the base metals into gold, and the composition of an elixir of immortality, were questions ardently studied by the Chinese. It is moreover a matter of history that intercourse between China and Persia was frequent both before and after the Mahommedan conquest of the latter country; that embassies from Persia, as well as from the Arabs, and even from the Greeks in Constantinople, visited the court of the Chinese emperor in Shansi; that Arab traders settled in China, and that there was frequent intercourse by sea, between China and the Persian Gulf; that China had an extensive alchemical literature anterior to the period when alchemy was studied in the West. All these facts go to prove that that pseudo-science originated not with the disciples of Mahommed, but that it was borrowed by them from the Chinese.

With regard to the Philosopher’s Stone, it is remarkable that while the alchemists of the West have spoken with doubt as to what it was, with the Chinese its identity appears hardly to have been questioned. That wonderful body which, when used as a chemical agent, was supposed to have the power of converting other metals into gold, and when employed as a medicine, of conferring immunity from death, is, according to the writings of the Chinese alchemists, Cinnabar.

Ko-hung, author of the Pau p’uh tsı’ p’ian, a work of the fourth century of undoubted genuineness, enumerates various mineral and vegetable productions possessing in different degrees the properties of an Elixir Vite. Of the first of them, Cinnabar, he writes in terms thus translated by Mr. Edkins:—

When vegetable matter is burnt, it is destroyed, but when the Tan sha, [Cinnabar] is subjected to heat, it produces mercury. After passing through other changes, it returns to its original form. It differs widely, therefore, from vegetable substances, and hence it has the power of making men live for ever, and raising them to the rank of the genii. He who knows this doctrine, is he not far above common men? In the world there are few that know it, and many that cavil at it. Many do not even know that mercury comes out of cinnabar. When told, they still refuse to believe it, saying that cinnabar is red, and how can it produce a white substance? They say also that cinnabar is a stone,—that stones when heated turn to ashes, and how then can anything else be expected of cinnabar? They cannot even reach this simple truth, much less can it be said of them, that they have been instructed in the doctrine of the genii.

The specimens of cinnabar which I have received are in small crystalline fragments and very pure. According to Kämpfer,† both native and artificial cinnabar are exported from China to Japan, the artificial being used by the Japanese as a colour, and the native been employed in medicine. The same author tells us that in his time, the buying and selling of cinnabar was a monopoly of certain merchants, in virtue of letters patent granted by the emperor.

* Transactions of the China Branch of the Royal Asiatic Society (Hong Kong), Part 5, 1855, art. iv.
銀硃 Pin-choo; Vermilion; Levigated Red Sulphuret of Mercury.—The process for preparing vermillion is described by an old Chinese author to be as follows:—1 lb. of mercury and 2 lbs. of sulphur are triturated together until they form a blackish powder, which is put into a crucible, closely covered with an iron lid and luted down. The heat of a wood fire is then applied, the lid being kept cool by something wet. The sublimation is thus effected, 1 lb. of mercury usually producing 14 ozs. of cinnabar of the first quality, and 3½ ozs. of the second. In the Library of the India House (London) is a series of beautiful native drawings representing the preparation of vermillion by the Chinese.

Chinese vermillion is an article of regular importation into London, where the finer qualities realize from 3s. 3d. to 3s. 6d. per lb.

黃升礬 Hwang-shing-yo; Nitrate of Mercury with some Peroxide.—A pale buff powder, wholly volatile.
NOTES ON CHINESE MATERIA MEDICA.

BY DANIEL HANBURY, F.L.S.

FRUITS AND SEEDS.

Hwa-tseaou is a name applied to the fruits of two species of Zanthoxylum, namely, Z. piperitum, D. C., and Z. alatum, Roxb.* The first is a native of Japan, in which country its fruits are used as a condiment; the second is indigenous to India and China, and, as proved by specimens obtained by my brother, Thomas Hanbury, of Shanghai, is the source of the Hwa-tseaou of the Chinese shops.

Zanthoxylum alatum, first noticed by Capt. Hardwicke, in 1796,† is a small tree occurring in various parts of Northern India, as in Oude, Rohilcund, Kumaon, Nepal, Sikkim, Bhotan, and Khasia, and extending far eastward into China. As may be expected from so extensive a range, it varies considerably, especially as to the size of its leaves and number of its leaflets, and the number and size of its spines; but the transition from one form to another is so gradual that no botanist who should examine a large series of specimens could doubt their belonging to a single type.

The fruits (fig. 1), as found in the Chinese shops, consist of the carpels usually dehiscing and empty, but sometimes enclosing the round, black, shining seed.

---

* I retain Roxburgh's name for this plant, because I am certain of its identity. Steudel superseded it by that of Z. acanthopodium, D. C.; but this latter is not identical, at least according to M. Alphonse de Candolle, who, at my request, has kindly compared it with specimens of Z. alatum, Roxb., from China.
† Asiatic Researches, vol. vi., p. 376.
In perfect specimens we find a slender pedicel supporting the carpels, which are normally four in number, but of which at least one or two are mostly abortive. The carpels are oval or nearly spherical,  4ths of an inch in longest dimension; externally they are of a bright reddish brown, covered with prominent tubercles filled with oleo-resin; internally they are furnished with a hard, papery, white membrane, which becomes loose, contracts and curls up when the seed falls. The drug has a peculiar aromatic taste, and, when crushed, an agreeable and highly aromatic odour—properties due to the oleo-resin contained in the outer part of the carpel.

The fruits of Zanthoxylum alatum, Roxb.,* have been subjected to chemical analysis by Dr. Stenhouse, who has obtained from them by distillation:—

1. An essential oil, to which the aromatic properties are chiefly due. This oil, which when pure is called by Dr Stenhouse Xanthoxylene, is a hydrocarbon isomeric with oil of turpentine. It is colourless, refracts light strongly, and has an agreeable aromatic odour; its composition is C_{10}H_{16}.

2. Xanthoxylin, a stearopten found floating on the water, distilled from the seeds, and also separable from the crude essential oil.

After repeated crystallizations from alcohol, xanthoxylin may be obtained in a state of purity, and then presents the form of large crystals of a fine silky lustre, insoluble in water, but readily soluble in alcohol or ether. It has a very slight odour of stearine, and a slightly aromatic taste. It distils unchanged, its fusing point before and after distillation remaining the same, namely 176° F., and its solidifying point 172.4° F. Its composition is C_{16}H_{18}O.

The fruits of Zanthoxylum alatum are used in China as well as in India as a condiment. The Fagara or Fagara minor of the old pharmacologists† is probably referrible to this species.

白蒺藜 Pih-teh-i-le; Carpels of Tribulus terrestris, L. (Zygophyllaceae); Pê ciê li, Cleyer, Med. simp., No. 28; Pun-tsaou, fig. 322.—These little spiny carpels have slightly astringent properties. Loureiro states that they are beneficial in haemorrhagia narium and in dysentery; also as the basis of a gargle in tenderness of the gums, and in ulcers and inflammation of the mouth and throat.

The herb was formerly officinal in Europe, but is now obsolete.

巴豆 Pa-tou; Fruits of Croton Tiglum, Lam. (Euphorbiaceae); Pâ tei, Cleyer, Med. simp., No. 224.

The seeds, from their drastic purgative properties, are regarded by the Chinese as extremely poisonous.

呂松果 Leu-sung-kuo; Seeds of Strychnos Ignatia, Juss. (Loganiaceae); Saint Ignatius Beans.—These well-known seeds are imported from the Philippines, in the Bisayas provinces of which islands, the tree which affords them is stated by Blanco, the author of the Flora de Filipinas, to be common. But neither this botanist nor any other has been able, that I am aware of, to procure complete specimens of the tree, so that it is as yet undescribed.

木鳖子 Muh-pii-te, also called Fan-muh-pii; Seeds of Muricia Cochinchinensis, Lour. (Cucurbitaceae); Pun-tsaou, fig. 387 and 386; Mō pι-te cu, No. 188, Cleyer.—Orbicular or obscurely triangular compressed seeds (fig. 2), tubercled at the margin, and having a dark brown, fragile, rugose testa.

---

* Erroneously supposed at the time to be those of Z. piperitum D.C.
frequently marked with depressed reticulations; in diameter they vary from $\frac{3}{4}$ to 1½ inches. The yellow cotyledons within are extremely oily.

According to Loureiro, the seeds and leaves of *Muricia Cochinchinensis* are aperient, and useful in the treatment of tumours and malignant ulcers, and of obstructions of the liver and spleen. The plant is a native of China and Cochin China; it is not enumerated in the Flora of Hong Kong,* and, I believe, has not been obtained by any collector in recent times. There is an indifferent specimen of Loureiro's in the British Museum.

Seeds of a cylindrical form, 2 to 3 lines long, pointed at one extremity, rounded at the other, of a dark brown colour with two light stripes on opposite sides.

**石栗** Sthit-leth; Seeds of *Aleurites triolba*, Forst. (*Euphorbiaceae*); *Juglans Camirium*, Loureiro.—The kernel of the seed yields abundance of oil.

**楮栗子** Choo-sith-tsze; The small seed-like nuts or achenes of *Broussonetia papyrifera*, Vent. (*Moraceae*), Paper Mulberry Tree.

These are roundish seed-like bodies somewhat smaller than the seeds of white mustard, slightly compressed and keeled on one side, of a pale brown, or, when fresh, orange colour. The fleshy part of the compound fruit is saccharine and edible; what virtues the seeds are supposed to possess, I do not know. The inner bark of the tree is used in Japan for the manufacture of paper, as is fully described by Kämpfer.†

**使君子** She-keun-tsze; Fruit of *Quisqualis indica*, L. (*Combretaceae*); *Pun-tsou*, fig. 385.

These fruits (fig. 3) are about an inch in length, oval or oblong, pointed at either extremity, and sharply pentagonal. The woody pericarp is thin, fragile, and of a deep mahogany colour, and encloses an oily seed. Loureiro states that the seeds used daily are recommended as an anthelmintic and in the rachitis of children.‡ Their anthelmintic properties, though recorded by Rumphius and several subsequent writers besides Loureiro, have not attracted much attention in Europe. Recently, however, Dr. E. J. Waring, of Travancore, has published a paper on some of the principal

---

* Bentham, *Flora Hongkongensis*, Lond., 1861, 8vo.
† *History of Japan* (Scheuchzer's translation), Lond., 1727, Appendix, p. 22.
‡ *Flor. Cochinch.*, p. 337.
indigenous anthelmintics of India, in which he has quoted some favourable reports of the properties of the seeds in question. From these it appears that the seeds are chiefly used against *lumbrici*, especially when occurring in children. They are sometimes given almost ad libitum, but generally the dose of four or five good seeds is found to be sufficient.

**訣子** *Ho-tsze;* 柯勒黎 *Ko-lih-le;* Fruits of *Terminalia Chebula Roxb.* (Combretaceae); Chebulic Myrobalans.

These fruits are well known in English commerce on account of their astringent properties, which render them valuable in various processes of dyeing. In medicine they have been held in esteem for ages, not only on account of their astringency, but also from their mildly purgative properties. Hill remarks that when given in substance they do not exert their purgative faculty at all, but are astringent only, whereas when administered in infusion or decoction they open the bowels in a very gentle and easy manner. In China, Europeans, I am informed, occasionally have recourse to myrobalans as an aperient—at the instance, I suppose, of native practitioners. The dose is from 2 to 4 drachms in infusion.

*Xanthium strumarium,* an almost ubiquitous weed in temperate and warm climates, is found both in China and Japan. Its leaves, under the name of *Herba Lapprae minoris,* were formerly official in Europe, and were administered internally in scrofula, herpes, &c., and externally as an application to scrofulous tumours.

Minute ovoid umbelliferous fruits; mericarps, with very prominent equal ribs, one vitta between each; commissure bi-vittate.

*Cnidium Monnierii* has been found by the Russian botanists in inundated spots on some of the islands of the Amoor, where, however, it does not appear to be a common plant. It also occurs in the neighbourhood of Pekin.

From 1 to 1½ inches long, ovoid or oblong, cylindrical, pointed at the upper extremity, less so at the lower. The testa is of a cinnamon-brown colour, woody and fragile, marked longitudinally with broad, shallow striae, and having a smooth scar at the base, near to which, and opposite each other are two small oblong prominences. The nucleus, which is deeply corrugated, is covered by a thin brown membrane; its base is marked by a conspicuous cicatrix.

The seeds of *Torreyia nucifera* are eaten like hazel nuts, and although reputed somewhat laxative, are considered wholesome. In Japan an oil is expressed from them, which is used for culinary purposes.

---

*Indian Annals of Medical Science,* No. 12 (1860).
† *History of the M. M.* Lond., 1751. 4to, p. 508. Myrobalans were included in the *Materia Medica* of the London Pharmacopoeia down to the year 1721.
NOTES ON CHINESE MATERIA MEDICA.

白葉 Pik-ko; 銀杏 Yin-häng (Silver-almond); Seeds of Salisburyia adiantifolia, Sm. (Taxineae).—Ginkgo biloba, L.; Ginkgo, arbor nucifera folio adiantino, Kämpf. Amen. p. 811; Pun-tsou, fig. 658.

These are nut-like, oval, pointed seeds, from ⅓ to an inch long, keeled lengthwise on two sides, and having a smooth, fragile, bony, pale brown, outer shell, or testa. The nucleus of the seed consists of amylaceous albumen enclosing a pair of long, narrow cotyledons, the whole enveloped in a delicate reddish-brown membrane.

Salisburyia adiantifolia is commonly cultivated both in China and Japan, where it attains a large size. The male plant was introduced into Europe about a century and a half ago; the female much more recently. The tree is not uncommon in gardens; and in the warmer parts of the Continent it ripens its handsome, plum-like, yellow fruits perfectly. The seeds, Kämpfer tells us, are eaten to promote digestion "ac tumetem ex cibo ventrem laxare!" The pulp, which has a penetrating offensive smell of butyric acid, has been chemically examined by Dr. Schwarzenbach,* who has extracted from it by means of ether a peculiar crystallizable fatty acid, which has been named Gingkoic acid, and which has the composition C₁₆₆ H₂₄ O₅ + HO. Gingkoic acid forms tufts of acicular crystals, which have not been obtained colourless, but are of a brownish-yellow; it is easily soluble in alcohol or ether, and exhibits in either case a strong acid reaction. It fuses at 95° F., and congeals at 50°. Heated with solution of potash, it formed a soap-like compound. The other constituents of the pulp are pectin, gum, glucose, citric acid, and chlorophyll.

大海子 Tu-hai-tsze; Fruits of Erioglossum or Nephelium? (Sepin-daceae); Boa-tam-paijang, Guibourt, Hist. des Droques, tome iii., page 543; Bungtalai (otherwise written Poung-ta-rai) of the Siamese.

This fruit is of some interest as having been introduced into France about twenty years ago as a certain specific in diarrhoea and dysentery. Its claims to this character, which were tested in the Hôpital Beaujon in Paris, did not however hold good, no results being obtained from its use, but such as were attributable to the effect of repose, diet, and a mucilaginous beverage. But the drug had the merit of an unknown origin, a barbarous name, and a very high price;+ and notwithstanding the unfavourable report made upon it by those officially appointed to give it a trial, it continued for some time to be prescribed.

Boa-tam-paijang, for such is the name under which it was introduced into Europe, though in Bangkok, whence I have received specimens, it is better known as Bungtalai, is produced in Cambodia, from a tree which has not at present been botanically determined. Sir Robert H. Schomburgk, British Consul at Bangkok, succeeded in obtaining fresh seeds, which germinated, but the young plants thus raised perished before attaining maturity. The leaves which Sir Robert sent me are about 5 inches long, simple, entire, oblong or ovate, acuminate, rounded or subcordate at the base, and perfectly glabrous on both sides. The fruits, as found in commerce (fig. 4), are from ⅗ to 1½ inches long, ovoid, usually somewhat elongated at the lower extremity, which terminates by a large oblique cicatrix. Externally they are of a dark brown, deeply wrinkled, though generally less so at the superior extremity. The pericarp, which is from ⅓ to ⅔ of an inch in thickness, consists of a thin epidermis,

+ In the wholesale price list of MM. Menier, druggists, of Paris (1854), it is quoted at 200 francs per kilogramme, i. e. £3 13s. per lb.
beneath which lies a dry, black, resinous-looking pulp, surrounding a fragile shell lined with a whitish membrane (the testa of the seed?). The central part of the fruit is occupied by two cotyledons, which in their dried and shrunken state are thin and concave: the radicle is inferior, very short and turbinate. When the fruit is macerated in water, its outer shell or pericarp increases enormously in volume, forming a large gelatinous mass.*

It is this mucilaginous property that confers a value on the fruit in the eyes of the inhabitants of China and Siam, in both which countries the jelly is sweetened and eaten as a delicacy.

Boa-tam-paijang has been analyzed by Professor Guibourt, and found to consist of the following substances:

- **In the pericarp.**
  - Green oil: 1.06
  - Bassorine: 59.04
  - Brown astringent matter: 64.90
  - Mucilage: 1.60
  - Woody fibre and epidermis: 3.20

- **In the nucleus.**
  - Fatty matter: 2.98
  - Saline and bitter extract: 0.21
  - Starch: 31.91
  - Cellular tissue: 35.10

Total: 100.00

---

**槐實** *Hwae-shih*; Legumes of *Sophora Japonica L. (Leguminose)*.

*Sophora japonica* is a tree of very common occurrence in China and Japan, and not uncommon in the gardens of Europe. Its flowers called *Hwae-hwea* are largely used in China for dyeing yellow, or rather for rendering blue cotton green,† and the legumes are said by Enlicher to have a similar application.‡

These latter, in the dried state, are from 1 to 4 inches long by \( \frac{1}{2} \) to \( \frac{3}{4} \) of an inch wide, wrinkled, fleshy, semi-transparent, more or less contracted between the seeds, which usually do not number more than six in each legume.

The valves of the broad, flat pods are regarded, according to Loureiro, as attenuant, stimulant, and purgative. They are also lauded for their effects in the removal of phlegm and other viscid humours, and in the form of a sternutatory or suppository are said to be peculiarly efficacious in apoplexy, hemiplegia, and paralysis.

---

* Sir R. H. Schomburgk has been told that where the trees grow by a road-side, their fruits sometimes drop to the ground so abundantly, that if they become wetted with rain, such a mass of glutinous jelly is formed as to render the passage of the road on foot or horseback a matter of difficulty.
‡ *Enchiridion Botanicum*, p. 677.
Chu kuh-tsu

These are flat, oval or reniform, black, one-seeded legumes, which being very small and indehiscent may readily be mistaken for seeds; they are about two lines long, and are sometimes surrounded by the calyx, which is 5-lobed and marked with prominent nerves. The fruits of this Psoralea have an aromatic flavour, and are used in India (of which country the plant is a native) as a stomachic, as well as in certain inveterate cutaneous diseases.*

Fe-tsoau-tou

These are smooth, black seeds (fig. 5), \( \frac{3}{4} \) of an inch in diameter, of a compressed spherical form, each furnished (when perfect) with a large, rigid, persistent podsperm. A transverse section shows a pair of plane cotyledons, between the flat sides of which and the thick and hard testa, lies a layer of black, horny albumen.

Fig. 5. (The figure in the centre shows the transverse section of a seed slightly magnified.)

Of the origin and application of this drug I have no information.

Che-ku-tse

The curiously-contorted, fleshy, fruit-bearing peduncle is edible, and said to have the flavour of pears. It is used in China and Japan to diminish the effects of an excess of wine.

Hae-kin-sha

A light, mobile, rufous-brown powder, which, when thrown into the air and ignited, burns like lycopodium, for which substance it might be substituted.

Che-kuh

My specimen of this drug consists of the fruit cut into halves and dried; in this state it forms circular discs of from 1 to 2 inches in diameter, nearly flat on the cut side, convex on the exterior. The peel is firm and excessively thick, being about half the diameter of the dried pulp: externally it is rough and of a deep blackish-brown, internally of pale buff. It is bitter and agreeably aromatic.

Loureiro states that Citrus fusca is widely diffused in Cochin China, but less common in China. He adds that the entire peel of the fruit is considered attenuant, debostreant, and mildly cathartic.

The zest of a thick-skinned orange or citron dried in very thin slices, is found in the Chinese drug shops under the name of Keiuh-pih.

In Tatarinov's Catalogue, these fruits are referred to Citrus microcarpa, Bge., a plant which Professor Bunge describes as "frutex in caldaris Pekmensibus frequens, fructu maturo mense Januario et Februario onustus." I do not know what further range this plant may have, but if it is only cultivated on a small scale with artificial heat, it can hardly be the source of a common drug like that under notice: I think it best therefore to leave the species of Citrus undefined.

The fruits called Tsing-pe are from ½ to ¾ of an inch in diameter, and resemble the Baccae Aurantii of European pharmacy, except that the latter have a somewhat less rough exterior.

Oval fruits of 1 to 1¼ inches in length, formed of six thin and papery valves, enclosing large, flat, obtusely-triangular, winged seeds. Each fruit is supported on a pedicel at least as long as itself.

In Tatarinov’s Catalogue the name Ma-tow-ling is referred to A. contorta Bunge, an identification I have not been able to confirm, though I have had the kind assistance of Professor Bunge. A. contorta is found in the neighbourhood of Pekin, and occurs also in the Amoor country.

兔絲子 Too-sze-tsze; Seeds of Cuscuta europaea L. (C. major Bauh.) (Convolvulaceaee); Pun-tsoau, fig. 379; Tú sū ʂà, Cleyer, Med. simp. No. 9; Tu-su-tsye, Tatarinov, Catal. Med. Sinens., p. 61.

Roundish seeds of a light brown colour, about the size of black mustard. The long filiform embryo, spirally rolled round the fleshy albumen, which is characteristic of the genus Cuscuta, may be readily seen if a seed be soaked in water and its testa then removed.

For the species of Cuscuta to which these seeds are referred, I adopt the authority of MM. Hoffmann and Schultes;† but although C. europaea is found in Japan, and probably occurs in China also, there is another species, C. chinensis Lam., the seeds of which I find to be extremely similar, so that it is very likely they may pass under the same native name. I am not aware what virtues are ascribed by the Chinese to this drug. The entire plant (Herba Cuscutae majoris) was formerly official in Europe as a purgative.

蓮子 Lien-tsze; Nuts of Nelumbium speciosum Willd. (Nelumbiaceae); Pun-tsoau, fig. 703.

These nuts, which in shape and size resemble small acorns, are produced by the well-known Nelumbium or Egyptian Bean, called in China Water Lily, a plant extensively cultivated both in that country and in India, as well for its ornamental flowers as for its various useful properties. The nuts have a farinaceous kernel, which, when boiled or roasted, is good to eat. The thick fleshy rhizome is likewise edible when cooked; the starch which it contains, separated by rasping and washing, constitutes a sort of arrowroot, called by the Chinese 藕粉 Gaou-fun.

菱 Ling; Fruits of Trapa bicornis L. (Haloragaceae); Pun-tsoau, fig. 704.

The plant is abundant on canals and shallow lakes, from the surface of which

* Mémoires présentés à l’Académie Impériale des Sciences de St. Pétersbourg, tome 2 (1835), p. 84.
its singular fruits (fig. 6) are collected in immense quantities, on account of their kernels, which, when roasted, are edible.

**Fig. 6.**

檓子 Che-tsze; 山栀 Shan-che; Dried Fruits of two or more species of Gardenia (Rubiaceae); Che-tsze, Pum-tsaoou, fig. 783; Czzi-tsy (Che-tsze), Fructus Gardenia floride, Tatarinov, Cat. Med. Sinens., p. 17.

Under the above Chinese names (otherwise spelt Tchi-tsei and Chan-tchi) I have received the dried fruits of two species of Gardenia.

The larger (fig. 7), called Che-tsze, occurs as a smooth, oblong, orange-brown, imperfectly two-celled berry, of from 1½ to 2 inches in length, crowned with the remains of the calyx, which are prolonged down the sides of the fruit in six prominent ribs. The pericarp is fragile and horny, marked internally by two narrow projecting receptacles. The seeds are numerous and imbedded in a dark orange pulp.

Dr. T. W. C. Martius has presented me with specimens of this fruit under the name of "Wongshey" (Whang-che and 黃栀), and refers it to Gardenia radicans Thunb.

The smaller fruit (fig. 8) called Shan-che, is from ½ to ¾ an inch in length, of an ovoid form, smooth, six-ribbed, furnished on the inner surface of the pericarp with two narrow wing-like receptacles opposite each other. The seeds are nidulant in an orange pulp.

The precise species of Gardenia affording each of these fruits is not yet clearly made out. There appear to be at least three plants, whose fruits are used on account of their colouring properties. These are:—

1. Gardenia floride L., a large, very ramous shrub, native of Japan, China, India, &c. Major Champion found it in abundance in several localities in Hong Kong. Mr. Fortune has informed me that it is common in the hilly districts at some distance from Shanghai, and that its fruit is collected for dyeing purposes, but not produced so abundantly as that of G. radicans.

2. Gardenia radicans Thunb., a much smaller plant than G. floride, with a

decumbent rooting stem. It is native of Japan, China, India, &c. Mr. Fortune has given me its Chinese name as Whang-tsze, and stated that its fruit is commonly collected in the north of China for its colouring properties.

3. Gardenia grandiflora Lour., a native of Cochin China. Loureiro mentions that its fruits impart a beautiful colour to silk, and that they are also used medicinally in decoction, in fevers and in a variety of other complaints.*

The fruits of these Chinese Gardenias (which are so similar in properties that the analysis of one will probably serve for the other two) have been examined by several chemists, among whom, as the most recent, may be mentioned Mr. Lorenz Mayer, of the laboratory of Professor Rochleder, of Prague. According to the investigations of this gentleman,† the splendid yellow colour of the Gardenia is due to a body named Crocine, which appears to be identical with the polychrome of saffron. Crocine is uncrystallizable; when in powder it is of a bright red colour; it dissolves readily in water or alcohol, its solution possessing the colour of chrome acid. Salts of lead give orange-red precipitates with a solution of crocine; if a concentrated aqueous solution be treated with sulphuric acid, the mixture assumes an indigo-blue colour, which changes to violet. By the decomposition of Crocine, a body called Crocetine is obtained. The composition of Crocine is \( (2\text{C}_9\text{H}_4\text{O}_5) + \text{HO} \); that of Crocetine, \( \text{C}_{42}\text{H}_{32}\text{O}_{11} \).

橄欖 Kan-ian; Fruits of two or more species of Canarium (Burseraceae) Pun-isau, fig. 668; Chinese Olive.

Most persons who have lived in China are acquainted with a small edible fruit, which, from its oblong shape and being generally preserved with salt, has acquired the name of Chinese Olive. The stones of this fruit are also well known from being frequently carved into beads and other ornaments. The Chinese olive, I need hardly observe, has not the least affinity with the true olive (Olea Europaea L.), but belongs to the natural order Burseraceae and genus Canarium. The precise species, for there are probably two or three, are not well made out. Loureiro describes in his genus Pimela, now referred to Canarium, two plants yielding edible fruits, namely, P. nigra (Canarium Pimela Konig and Sims, Annals of Botany, vol. i., 1805, p. 361, tab. 7, fig. 1) and P. alba (Canarium album Raueschel, Nomenclator Botanicus, ed. 3, 1797 p. 287).

Dried specimens of the fruits of these plants were presented to me by the late Mr. Reeves. That of Pimela nigra is an oval drupe \( \frac{1}{2} \) inches long, covered with a smooth black skin. The pulp, which is rather firm, surrounds a large, obscurely triangular, pointed stone. The fruit of Pimela alba resembles that of P. nigra, except that it is of a pale brown and has its outer skin much corrugated by drying.

Besides these and probably distinct from them, there are, according to my friend Mr. Lockhart, two other fruits used by the Chinese and commonly sold at certain seasons, the one at Shanghai, the other at Foo-chow. As I have not seen either of these fruits, I can offer no opinion upon them; but to those resident in the districts in question, I would address the request for specimens, including the pressed and dried flowers and leaves of the plants, in order that their botanical names may be determined. It is also desirable to ascertain in each case, how the fruit is used by the Chinese, by what names it is known and if the tree is cultivated or grows spontaneously.

NOTES ON CHINESE MATERIA MEDICA.

川煉子 Chuen-lëen-tsze; Fruits of Melia sp. (Meliaceae); Czuan-lan-tsy, Tatarinov, Catal. Med. Sinens., p. 15; Pun-tsao, fig. 745.

A fleshy, globular drupe about an inch in diameter, covered with a shining, thin, horny, yellowish-brown skin, within which, surrounded by dried pulpy matter, is a large stony endocarp, furrowed longitudinally and containing seven or eight cells, of which however, not more than six are usually developed. Loureiro gives Xin-lien (Chuen-lien) as the Chinese name of Melia Azedarach L., but the fruits of that tree are five-celled and much smaller than those in question. The drug under notice is used in China as a vermifuge.

大楓子 Ta-fung-tsze; Seeds of Chaulmoogra sp. (Pangieæ); Pun-tsao, fig. 773; Da-fyn-tsy, Tatarinov, Cat. Med. Sinens., p. 19.

These seeds (fig. 9), which are imported into China from Siam, are from 4ths to 3ths of an inch long, of an oblong or ovoid shape, very irregular, owing to mutual pressure in the fruit of which they formed a part. They consist of a hard woody outer shell (testa), to whose surface, portions of firm, dry pulp, or of the rind of the fruit, are often adherent,—sometimes so as to unite two or three seeds into a mass. The albumen is oily and encloses large, heart-shaped, leafy cotyledons.

The plant affording these seeds is not well ascertained. It is doubtless a species of Chaulmoogra; probably, judging from the resemblance of the seeds, nearly allied to the Indian C. odorata Roxb. The seeds of the latter plant are larger, and have a thinner and smoother testa than is the case with those found in the Chinese shops. Both seeds have a reputation as a remedy in skin complaints, especially in that most frightful of eastern diseases, leprosy. Dr. Hobson, late of the Canton Hospital, whose experiments appear to have been made with the seeds of the Indian Chaulmoogra, reports respecting them,* that he has found them to effect a cure in mild cases of leprosy, not of long standing; that the remedy (consisting of the powdered, oily nucleus of the seed) was administered in one-drachm doses twice a day during a period of four months or more, and that the expressed oil of the seeds was occasionally rubbed on the affected surfaces. The first appearance of improvement observed, was in the eruption becoming less prominent and red, minute white scales appearing round the circumference of the patches and the central parts assuming the character of healthy skin. Saline aperients are to be administered occasionally during the course of treatment.

蓮翅 Lëen-keaou; Fruits of Forsythia suspensa Vahl. (Oleaceæ); Siebold et Zuccarini, Flora Japonica, p. 10, t. 3.

As found in Chinese commerce, these are little, boat-shaped, brown capsules, 1/4 to 1/3 of an inch long, with a thin longitudinal partition. They constitute the valves of the fruit, which, in its perfect state, is thus described by Endlicher:—“Capsula ovata, compressiwsula, subligiosa, corticata, bilocularis, loculicidobivalvis, valvis planisculis, medio septiferis. Semina in loculis paucis, pendula,

compressa; testa membranacea hinc in alam angustam, inde in marginem angustissimam expansa. Embryo in axi albuminis carnosi, parci rectus; cotyledonibus foliaceis, radicula brevi, cylindrica, supera."*

I know not what virtues are ascribed to this drug: it appears to be devoid of any important property.

**Woo-tung-tsze; Seeds of Sterculia plantanifolia Lin. fil. (Sterculiaceae).**

Spherical, about the size of peas, externally covered with a shrivelled, shining, pale-brown skin.

**Péih-ching-kea; Berries of Daphnidium Cubeba N. ab E. (Laurinæ); Laurus Cubeba Lour.; Cây Mang thang (Cochinchinese).**

The Chinese name Péih-ching-kea, under which I have received these berries, appears to be also applied to cubeds; and in fact, if one may judge from the wood-cut in the Fun-tsou (fig. 690), it is to the latter drug that it properly belongs. Whether the Chinese confound the two and use them indiscriminately, or whether they consider one as a mere variety of the other, I am unable to say. The friend who obtained one specimen in my possession, presented it to me marked "Cubeds," and I believe he is not the only person who has fallen into such an error. M. Rondot, in his Commerce d'Exportation de la Chine (Paris, 1848) enumerates cubeds as a production not only of Java, but of China likewise; he also mentions that the Chinese cubeds are exported exclusively to India, whence we may conclude that they are not suitable for European markets. Are not these Chinese cubeds the drug under notice?

The drug which I have received consists of small berries, which, in size, form, and general appearance, much resemble peppercorns or cubeds; examined attentively, however, they are seen to be one-seeded globular berries (fig. 10) attached to a pedicel sometimes half an inch long; at the base of each berry traces of the perianth are visible. The pericarp is thin, fleshy, and in the dried state, corrugated. The seed is globular, with its cartilaginous, shining brown testa surrounded longitudinally by a narrow ridge. The cotyledons are hemispherical, thick, and oily; the radicle superior.

In endeavouring to assign a botanical origin to this drug, I have been guided chiefly by two considerations:—1. The evident laurineous structure of the berries. 2. Their superficial resemblance to cubeds. Turning to Loureiro's Flora Cochinchinensis, we find, under the name Laurus Cubeba, a tree described, the fruit of which so remarkably coincides with the drug under notice, that I cannot but conclude the two are identical. This tree was transferred by Nees ab Esenbeck, in his Systema Laurinarum, to the genus Daphnidium, but he borrowed the description of it from Loureiro, and had evidently examined no specimen—in fact, it is apparently unknown to

recent botanists. Loureiro describes its fruit as "Bacca globosa, nigra, pedunculata, minima: semine globoso." He adds that the berries are strengthening, cephalic, stomachic, and carminative, and that in decoction they are useful in vertigo, hysterical affections, paralysis, melancholy, and impaired memory—properties which are possessed by the bark, though to a less degree. The fresh fruits are used for the preserving of fish. The odour of the berries is fragrant, their taste is aromatic, and somewhat pungent, and occasions a flow of saliva. They have the size, form, and colour of black pepper. Each berry is attached to a slender, rather long pedicel, whence they might be called not inappropriately *Piper caudatum*.

*Daphnidiun Cubeba* is cultivated in Cochin China, and probably in Southern China also. Loureiro omits to give its Chinese name.

牙皂 *Ya-tsaou*; Legumes of *Prosopis*! (*Leguminose*); *Ya Cao* Clever, *Med. Simp.*, No. 223.

These are the pods of some leguminous tree at present undetermined, but which, judging from analogy, is probably not far distant from the genus *Prosopis*. They are from two to four inches long, and from $\frac{1}{2}$ to $\frac{3}{4}$ of an inch broad, more or less sickle-shaped and compressed, their upper edge prolonged into a narrow wing. The anterior extremity is pointed, the posterior attenuated into a sort of stalk. The pods are indehiscent, and have thick, pulpy valves, which are externally smooth and of a deep brown. The substance of the pod, when chewed, even in very small quantity, produces an extremely disagreeable sense of acidity in the fauces. Its properties are thus quaintly described by Clever: "Intrat hepar et stomachum. Catarrhos solvit. Aperitivum est measum. Tumores complanat." The drug is said to be produced in the province of Szechuen.

Although this species of cardamom, as well as those that follow, have already been described and figured in the *Pharmaceutical Journal*, it will probably add to the value of this paper, if I briefly recapitulate the characters by which they are distinguished, and the chief points of interest attaching to them.

The *Large Round China Cardamom* varies considerably in size, my specimens being from $\frac{1}{4}$ to $\frac{3}{4}$ of an inch in length. The capsules are somewhat oval or globular, pointed at either extremity, obscurely three-sided (except at the base, where the triangular character is strongly marked); they are sometimes attached to a long pedicel. The pericarp closely invests the mass of seeds; it is brown, and strongly marked by interrupted longitudinal ridges; it is hardly aromatic. The seeds are coherent into a three-lobed mass; they are generally light greyish-brown, somewhat oblong and angular, with a deep furrow on one side; they have a slight aromatic odour and taste, the latter suggestive of thyme, though much weaker. This cardamom, as generally met with in the Chinese shops, has been deprived of its husk. It is a native of the South of China and of Cochin China, whence it is exported. It appears to be much employed in Chinese medicine as a stomachic, but it must be very inferior in power to some other species.

Small Round China Cardamom.—*Cardamome ronde de la Chine*—Guibourt, *Hist. des Drogi.*, éd. 4, tome ii. (1849), p. 215, fig. 113, 114 (excluding other synonyms); *Pharm. Journ.*, xiv., 354, fig. 3.

A smaller fruit than the preceding, which it much resembles. The following description of it is taken from M. Guibourt's *Histoire des Droges*:

* "On some Rare Kinds of Cardamom." *Pharm. Journ.*, xiv., 352; also, Journ. de Pharmacie et de Chimie, Mai et Juin, 1855; Bonplandia, 1 Juni, 1855.
"Capsules pedicelled, nearly spherical, from seven to eight lines in diameter, slightly striated longitudinally and much wrinkled in all directions by drying; it is probable, however, that the fruit was smooth when recent. The capsule is thin, light, easily torn, yellowish externally, white within. The seeds form a globular coherent mass. They are rather large and few in number, somewhat wedge-shaped, of an ashy-grey, a little granular on the surface and present on the outer face a bifurcate furrow, shaped like a Y. They possess a strongly aromatic odour and taste."

To this description I may add that, compared with the Large Round China Cardamom, the capsules in question are more wrinkled in a network manner, more fragile and thin, and (from immaturity?) much less adherent to the mass of seeds; they are more globose, not triangular at the base, but flat, or even depressed like an apple. Their colour, in all the specimens I have seen, is a brownish-yellow. I cannot confirm M. Guibourt's remark as to the highly aromatic properties of the seeds.

This cardamom, which appears to bear the same Chinese name as the foregoing, is attributed by M. Guibourt to the Amomum globosum of Loureiro.

The Ovoid China Cardamom is a product of Southern China, and abundant in the drug shops of Singapore, as well as in those of China. It is an oval or oblong, three-celled, three-valved and obscurely three-sided fruit, of from 1 to 1½ inches in length. The pericarp is of a dusky greyish-brown, deeply striated longitudinally, thick and coriaceous, frequently covered on the surface with a whitish efflorescence; it is but slightly aromatic. The seeds are very large, often upwards of three lines in length, sharply angular, hard and striated, having a powerful and peculiar aromatic smell and taste.

The seeds of the Ovoid China Cardamom are used by the Chinese for a variety of disorders, and, according to Loureiro, are also employed as a condiment.

Amomum medium is a plant known at present only through an unsatisfactory description by Loureiro in his Flora Cochinchenensis.

砂仁殼 Sha-jin-kō.—Capsules (deprived of seeds) of Amomum xanthioides Wallich. (Scitamineae); husks of the Xanthioid Cardamom. Pharm. Journ., xiv., 418, fig. 7.

These empty capsules are mostly attached to a common stalk, which, when perfect, is about five inches long and beset with the remains of sheathing bracts. The superior portion, which is much stouter than the rest, bears the fruits closely crowded together on short, bracted pedicels. No bunch in my possession bears more than twelve fruits, but from the number of pedicels on some specimens it would appear that the flowers at least are often twice as numerous. The capsules having been deprived of seeds are shrunk and compressed, but after soaking in boiling water they acquire their proper volume, becoming nearly spherical and about three-quarters of an inch in diameter. The pericarp is covered with long, acute, recurved spines, which are longest near the base.

Amomum xanthioides is a native of Burmah, where it was discovered by Wallich in 1827. It also occurs in the Laos country and Cambodia, where its fruits are collected for use. The plant being but little known, it was with much pleasure that I learned from Sir R. H. Schomburgk, by a note under date March 28, 1861, that he had just succeeded, after many endeavours, in procuring living specimens, which he had in cultivation at Bangkok, and from which he hoped to obtain flowers and fruits. The seeds of A. xanthioides deprived of their pericarp
are sometimes sold in the London market as Malabar Cardamoms, for which they are not a bad substitute. To what uses the Chinese apply the husks, which are devoid of aroma, I am unable to say.

A small scitamineous fruit supposed to be that of Loureiro’s Anomum villosum, a Cochinchinese plant, of which very little is known. It is sometimes sold attached to the stalk, sometimes removed from it. The scape, which, when perfect, is about three inches long and reclinate, bears as many as eight or ten capsules upon its superior extremity. The capsules are from six to ten lines in length. In the dried state they are oval, occasionally nearly spherical, more or less three-sided, bluntly pointed, with a scar at the summit, rounded at the base, and attached by a pedicel one to two lines long. The pericarp is externally dark brown, marked with obscure longitudinal striae and covered with asperities, which, after soaking in water, are seen to be short, thick, fleshy, closely-crowded spines. It has, when bruised, an aromatic and tar-like odour; the seeds have a similar tar-like odour and taste, not unmixed with the aromatic warmth of the Malabar Cardamom; they are angular, and upon removal of the pericarp, remain united in a three-lobed mass. The scape is densely villous; the pericarp of the immature fruit is slightly so, but in the mature fruits this character is not observable.

This Cardamom is said to grow in the province of Kwang-tung, and in the Yang-yun district of Southern China. It appears to be frequently used in medicine by the Chinese, and is, no doubt, a good representative of the Elettaria Cardamom officinal in Europe.

益智子 Yth-che-tsze.—Bitter-seeded Cardamom. Pharm. Journ., xiv., p. 418, fig. 8; Fun-tsaou, fig. 173.

The capsules are mostly oval, some ovate-oblong, and a few nearly spherical, pointed at the extremities, six to ten lines long. The pericarp is of a deep dusky brown, coriaceous, devoid of hairs, beset longitudinally with interrupted ridges usually about eighteen in number; it has an agreeable aromatic smell and taste. The seeds are obtusely angular and adhere firmly together; they are distinguished by an aromatic, bitter, myrrh-like taste.

It is not known what plant produces this little fruit. The MS. catalogue of the collection of Chinese drugs at the Royal College of Physicians of London, mentions the province of Kwang-tung as its place of growth, and it is also said to grow in the island of Hainan.

高良薑子 Kaou-leang-keang-tsze.—紅豆蔻 Hung-tow-kow.—Fruits of Alpinia Galanga Willd. (Scitamineae); Galanga Cardamom, Pharm. Journ., xiv., 420, fig. 10, 11.

Capsules about half an inch in length, of an oblong form, somewhat constricted in the middle, or occasionally pear-shaped; some are obscurely three-sided. Each fruit is prominently crowned with the remains of the calyx; in a few, the lower extremity is still attached to a slender pedicel. Most of the capsules are much shrivelled on the outside, apparently from having been gathered while immature; a few, however, retain a plump and smooth appearance. The pericarp varies externally in colour according to its maturity, from a pale to a deep reddish-brown; internally it is whitish. It is glabrous; in the mature fruits thin and brittle, not splitting into valves; in the shrivelled fruits it appears stronger, from its close adherence to the mass of seeds. Upon removal of the pericarp the seeds are seen united in a three-lobed mass, completely invested in a whitish integument, each cell or lobe containing, usually, two seeds, placed one above the other. The seeds are ash-coloured,
flattish, and somewhat three-cornered; finely striated externally towards a large conspicuous hilum which faces the wall of the capsule, and which is connected with the axillary placenta by a long, broad funiculus. Each seed is nearly surrounded by a tough aril; opposite the hilum a scar-like depression is observable. The seeds have a pungent, burning taste, and aroma resembling the Larger Galangal Root; the pericarp is similarly aromatic and biting.

Authentic specimens of the fruit of Alpinia galanga grown in the Calcutta Botanic Garden, and kindly placed at my disposal by Dr. Thomson, are identical with the Chinese drug.

東坡荳蔻 Tung-po-tow-kow.—Round or Cluster Cardamom. Fruit of Amomum Cardamomum L. (Scitaminee); also called in Chinese Hang-kow, Seaoou-kow, &c.

A well-known fruit, described in all the larger works on Materia Medica, but which in recent times had become rare, its place being supplied by the Malabar Cardamom (Elettaria Cardamomum Maton), the seeds of which are very similar in odour and taste. Since, however, the opening of Siam to European commerce, Round Cardamoms have been frequently imported into London from Bangkok.
NOTES ON CHINESE MATERIA MEDICA.
BY DANIEL HANBURY, F.L.S.

ROOTS.

 Yapı-kin.—Tubers of a species of Curcuma (Scitamineae); Pun-tesao, fig. 179; Tatarinov, Catal. Med. Sinens., p. 32; Yō kin, Cleyer, Med. Simp., No. 65.

Oblong or ovate tubers (fig. 11) tapering at either end, from ⅝ to 1 ½ inches in length, covered externally with a thin, adherent, brownish-grey cuticle, usually (but not invariably) smooth. When broken, they exhibit a shining fracture, and are seen to consist of a hard, semi-transparent, horny, orange-yellow substance, easily separable into two portions, an inner and an outer. The tubers have an aromatic odour, and a slight taste resembling turmeric, and contain an abundance of starch.

Many scitamineous plants produce at the extremities of the roots springing from the rhizome, starchy tubers such as those above described. Dr. Roxburgh calls them pendulous tubers, from their descending into the ground beneath the rhizome.† They are usually less aromatic, and more amylaceous, than the rhizome: from those of some species of Curcuma, the so-called East Indian Arrow-root is manufactured.

The plant producing Yapı-kin is undetermined; it is a native of the south of China, and is most probably a species of Curcuma.

Yē-chū; Rhizome of Bambusa Arundo Nees (Gramineae); Yē chō, Arundo Bambus Lour. (non Linn.)

This drug consists of a rhizome of a pale yellowish-brown colour and somewhat translucent, in contorted pieces of some inches in length, flattened or nearly cylindrical, ⅛ to ⅓ of an inch in greatest diameter, marked with concentric rings at unequal distances, and dotted with the remains of radical fibres. The pieces are moist, compressible and flexible, but break readily with a short fracture. They have a sweetish, mucilaginous taste, with but little odour. When macerated in water, they regain their natural dimensions, becoming three times as thick as in the dry state. The root and young shoots of this bamboo are stated by Loureiro, in the medical language of the day, to be resolvent and attenuant, to promote diaphoresis and diuresis, to purify the blood, &c., &c.

* Paris, 1848, p. 83.
† See figures given by Rumphius, Kämpfer, Roscoe, and others.
Tsang-shih; Rhizome of Atractyloides sp. (Compositae); Pun-tsaou, fig. 102.

Portions of a rhizome from 1 to 2 of an inch in diameter, occurring in oblong, jointed, occasionally branching pieces, of 1 to 2 inches in length. They are invested with a rough, brown cuticle, and some pieces are beset with radical fibres. The cut surface exhibits a spongy whitish substance, scattered through which, cells filled with resinous-looking matter of a deep orange colour may be seen with a lens.* Tsang-shih has a slightly aromatic odour, though but little taste. It is enumerated among the drugs of Kiang nan and Hoo-kwang. According to MM. Hoffmann and Schultes,† three species of Atractyloides, namely A. lancea D. C., A. lyrata S. et Z., and A. ovata D. C., are known by the Chinese name above given. Thunberg, who describes two of them under the genus Atractylis, does not allude to their possessing medicinal properties.

Heuen-sang; Huien sen, Cleyer, Med. Simp., No. 44; Pun-tsaou, fig. 110; Suan-sen, Tatarinov, Cat. Med. Sinens, p. 48.

Fleshy roots of about 4 inches in length and one inch in diameter at the middle, whence they taper to either extremity. They are longitudinally wrinkled and furrowed, and covered with an adherent brown cuticle; internally, they are fleshy and black; they have a sweetish taste and but little odour.

Yen-hoo-sit; Tubers of Corydalis ambigua Chamisso et Schlchtendal in Lunea, t. i. (1816), p. 558 (Fumariae); Pun-tsaou, fig. 133.

Little, hard, brown tubers, of somewhat flattened spherical form, averaging half an inch in diameter. Externally, they are covered with a thin wrinkled cuticle; when broken, they exhibit a bright yellow, semi-transparent, waxy appearance.

Corydalis ambigua Cham. et Schl., from which, according to Messrs. Hoffmann and Schultes,‡ this drug is derived, is a plant of Siberia and Kantschatka, throwing up its flowers upon the melting of the snow in early spring; it is also found in the Amoor country. I am indebted to Dr. E. Regel, of St. Petersbourg, for an authentic specimen of the tubers of this plant, comparison of which with the Chinese drug is confirmatory of their identity.

Mih-mun-tung; Tubers of Ophiopogon Japonicus Ker (Smilaces); Convallaria Japonica L.; Mondo Kempt., Amen., p. 823, with fig.; Pun-tsaou, fig. 268; Mih-mun tum, Cleyer, Med. Simp., No. 14.

This drug consists of cylindrical fleshy tubers, from 1 to 2 inches in length, and from 1 to 2 of an inch in diameter, tapering at either extremity (fig. 12). They are of a pale yellowish grey colour and translucent; somewhat shrivelled through drying, soft, flexible, yet easily broken. A central ligneous cord, resembling a stiff thread, runs longitudinally through each. The tubers have a slightly saccharine and aromatic taste, with a somewhat terebinthious not unpleasant odour. Their aqueous decoction is not rendered blue by iodine.

Ophiopogon Japonicus, a low perennial with a creeping rhizome, produces

---

* This resinous-looking matter is not removed by water, alcohol, or ether.
small tubers as expansions of the radical fibres: that they are really identical with the drug found in the Chinese shops, I have been able to convince myself by actual comparison. Kämpfer, who figures the plant well, states that a second species called in Japanese Temondo, and common in the province of Satzuma, produces larger tubers, and is therefore preferred. Two varieties of *Ophiopogon Japonicus* are described by Thunberg;* one of them may possibly be identical with Kämpfer’s Temondo. According to Loureo, the tubers of his *Commelina medica* (Aneilema R. Br.) are called *Měi-mùn-tung*.

The drug under notice is in frequent use among the Chinese, the candied tubers being eaten as a medicine.

These, like the preceding, are fleshy, translucent, yellowish-brown tubers, of the thickness of a writing quill to that of the little finger, and often 3½ inches in length. They are usually flattened, and more or less contorted and longitudinally furrowed. They have a mucilaginous, slightly saccharine taste, but do not possess any marked odour.

Loureiro states that this drug is regarded as diaphoretic and expectorant, and that it is administered in phthisis and also (in the form of decoction?) to allay feverish thirst and heat. It is also preserved with sugar as a sweetmeat. It appears to be produced in the province of Chekiang. According to Loureo, the plant is frequent in dry hedges both in Cochín China and China.

This root is collected in enormous quantities in the mountains of Cashmere, whence it is conveyed to Calcutta and Bombay, and there shipped for China.

The drug has a pungent, aromatic taste, with an odour resembling that oforris root. There is an excellent account of it, with a figure, in Professor Guibourt’s *Histoire des Droques*, tome iii., p. 25.

**川烏** *Chuen-woo*; Root of *Aconitum* sp. (*Ranunculaceae*). Conical or top-shaped tuberous roots (fig. 13), about 1½ inches in length, covered with a blackish brown cuticle; internally they are white and amylaceous. They taste slightly bitter, and leave a persistent sensation of numbness and tingling on the tongue, with some acridity in the throat.

Ground to powder, and mixed with an equal quantity of the root *Tsao-woo* (next described) and of the flowers *Naou-yang-hua*, also in powder, a compound is obtained which is reputed to produce local anaesthesia. This powder, moistened, is to be applied to the surface of the part to be operated upon for two hours previous to the operation, by which means, it is alleged, insensibility to pain will be produced.

**草烏** *Tsou-woo*; Root of *Aconitum Japonicum* Thunb.; Tatarinov, *Catal. Med. Sinens.*, p. 5. Blackish tuberous roots analogous to the last, but smaller in size and less regular in

---

* *Flora Japonica*, p. 139.
form (fig. 14). They are from \( \frac{1}{4} \) of an inch to upwards of one inch in length, and from \( \frac{1}{4} \) to \( \frac{1}{2} \) of an inch in diameter; oblong or ovoid, either tapering or rounded at their extremities, covered with a smooth or furrowed blackish cuticle; internally, they are white and inodorous. They are used with the preceding for producing insensibility to the pain of a surgical operation. According to Dr. Christison,* they are also the basis of an extract used to poison the arrows employed for killing game. Dr. C., who examined some of this extract, reported that it had evidently been prepared with care and skill, and that a minute portion of it, applied to the tongue or lips, occasioned an intense sensation of numbness and tingling.

This aconite root is said to be produced in the province of Chekiang; I refer it to *Aconitum Japonicum* Thunb. upon the authority of MM. Hoffmann and Schultes,† but it is highly probable the Chinese name is not restricted to a single species.‡

A grey, brittle root, of the thickness of a goose quill, whitish and farinaceous internally. It has a slightly aromatic taste, with but little smell: referred to an *Aristolochia* in Tatarinov's Catalogue.

A rhizome, the size of the little finger (fig. 15), occurring in pieces often four inches long; the upper side is flattened, or even somewhat channelled, beset with coarse, adpressed, ascending, rufous or yellowish hairs, which pass into scales at the once growing extremity, where also the remains of a stem rising at a right angle from the rhizome sometimes occur. The under side is convex, and covered with thick radical fibres, or more usually with their scars. The drug has but little taste and smell: it is brought from the province of Shansi. The plant is enumerated by Maximowicz in the Flora of Pekin.§

---

‡ Maximowicz enumerates nine species of *Aconitum* as occurring in the region of the Amoor, four in the neighbourhood of Pekin, and three in Mongolia.—*Primitia Flora Amurensis*, St. Petersburg, 1859.
NOTES ON CHINESE MATERIA MEDICA.

於赤 Yū-shūh; Root of a plant of the nat. ord. Umbelliferae?
Contorted fleshy roots, anteriorly about ¼ of an inch thick, but lower down swelled into nodular tubers, an inch or two in diameter, covered everywhere with a wrinkled brown skin; internally they are of a pale rusty colour, moist and easily cut, and have an aromatic odour and sweetish aromatic taste.

Nodular masses consisting apparently of the rootstock of some umbelliferous plant allied to Angelica. The specimens are from 1½ to 2½ inches in diameter, having a very irregular, rough, brown, outer surface, and a pale yellowish-brown, cavernous interior.
The odour of the drug resembles that of the root Tang-kwei (next described). A decoction of these two roots is taken daily by the Chinese women for some time previous to childbirth, under the idea that it diminishes the dangers incident to such a state.

當歸 Tang-kwei; Root of Aralia edulis S. et Z. (Umbelliferae), Flora Japonica, tab. 25; Doku quatz, vulgo Dosjen, Kempf., Amen., p. 826; Pun-tsaou, fig. 155.
This is a fleshy branching root, in size, shape, colour, and general appearance somewhat resembling gentian. It is internally whitish, has a sweetish, aromatic taste, and an odour approaching that of celery or angelica. It is said to be brought from the western provinces of China.
In Japan, according to Von Siebold, Aralia edulis is universally cultivated in fields and gardens, where it attains a height of three or four feet, flowering in August and ripening its blush-black berries in November. It is valued chiefly on account of its root, which is eaten like Scorzonera, but the young stalks are likewise a delicious vegetable.

人參 Jin-säng; Root of Panax Ginseng C. A. Meyer (Araliaceae) fide Horaninow; Pun-tsaou, fig. 90; Ginseng Root.
The most esteemed variety of this famous drug is that obtained from Corea, but good qualities are produced also in Mongolia, Manchouria, and other mountainous parts of the Chinese empire. The American ginseng imported into China is the root of Panax quinquefolium L.; it is much less esteemed than the native drug. Ginseng is regarded by the Chinese as the most potent of restoratives, and the finer qualities realize extravagant prices.* Its medicinal value appears, however, to the European practitioner entirely overrated, the root being simply mucilaginous, aromatic, and slightly bitter and saccharine.

升麻 Shing-ma; Rhizome of Thalictrum rubellum S. et Z. (Ranunculaceae); Szen-ma, Tatarinov, Cat. Med. Sinens., p. 53; Pun-isaou, fig. 130; Sien mao, Clever, Med. Simp., No. 90.
It is said to be produced in the province of Shan-si.

茅慈菇 Mow-tsze-kuo. The pseudo-bulbs of an orchideous plant; they are more or less ovate, shrunked, translucent, and horny; they vary in length from ¼ an inch to 1½ inches.
光菇 Kwang-kuo; Small bulbs resembling those of a Tulip; they are about ¼ of an inch long, smooth, and of a buff colour. The thin enveloping outer membrane has been removed; when cut, the external scale is seen to be very thick.

* See the interesting account of a Ginseng merchant contained in Mr. Lockhart’s Medical Missionary in China, ed. 2, p. 107.
小環蘮 Seaou-hwan-chai; Rhizome in size and form resembling that of Triticum repens (Radix graminea), of a bright yellow colour, tasteless, and inodorous. It is said to be derived from an aquatic plant inhabiting Cochin-china. I have not been able to identify the Chinese name, nor do I know the uses of the drug.

生半夏 Sang-pwan-hea; Tubers (tuber-buds) from the leaves of *Pinellia tuberifera* Tenore (Aroidae); *Arisema ternatum* Schott, Meletemata Botanica, 1839, i. p. 17; *Pun-tsoou*, fig. 357?

Under the name of Sang-pwan-hea, there occur in the Chinese shops certain tubers (fig. 16) having the aspect of little balls about half an inch in diameter, flattened on one side, and in colour of a dirty white. More closely examined, we perceive on the flattened side a depression or sort of umbilicus, attached to which the remains of an enveloping membrane may sometimes be found. Around the depression, and extending over half the tuber, are a number of little pits. The tubers are brittle, yet soft enough to be easily cut with a knife. Their cut surface is perfectly white, and shows no trace of concentric layers, or other structure than an uniform mass of starchy, cellular tissue.

Mr. H. G. Schott, of Vienna, an authority of the highest eminence on Aroidae, has obligingly examined these tubers, and has suggested that they are produced by *Pinellia tuberifera* Tenore, a plant of wide distribution in China, as well as in Japan.

The name Pwan-hea (sang signifies crude) appears to be applied to several species of Arum.

Hard, whitish tubers, ½ an inch to 1½ inches across, of flattened spherical form, having a depression, generally surrounded with little pits, on the upper surface, marking the situation of the bud. Many of the larger tubers have smaller ones branching from them. In the dry state the drug has but little smell and taste; yet when chewed, even in minute quantity, it proves exceedingly acrid. Both Cleyer and Loureiro† enumerate many virtues ascribed to this drug, but they are too indefinite to merit much attention.

This drug resembles the preceding (Sang-pwan-hea), but the tubers of this attain much larger dimensions and are far less regular in form and size.

WOODS, BARKS, &C.

沉香 Chin-heang; Wood of *Aquilaria Agallocha* Roxb. (Aquilarineae); Chin hiam, Cleyer Med. SImp., No. 208; Sinkoo, Kämpfer Amanitae, p. 903; Agallochum, Calambac, Agila Wood, Aloe Wood.

The history of this celebrated substance, which is the Aloe or Lign Aloe of the Scriptures, is so replete with interest, that it is difficult to bring within due

---

* The plant to which Kämpfer (Aman, p. 786) applies these characters is the *Arum triphyllum* of Thunberg's *Flora Japonica*, p. 233.
bounds even the most succinct account of it. I will, therefore, refer the reader who wishes for further information to the authors cited below.*

It may in the first place be observed that this, the Biblical Aloes, has no relation with the extract now called by that name, and that it does not possess even the most well-known character of that drug—intense bitterness. Aloes wood is the produce of Agularia Agullocha Roxb., a tree of vast size, growing in the mountainous parts of Cochinchina, the Laos country, and adjoining regions, and extending westward into Silhet and Assam. The wood in its ordinary state is not valued as a drug, being pale in colour, light, and inodorous. But under certain conditions a change takes place in portions of both trunk and branches, the wood becoming gorged with a dark, resinous, aromatic juice, and acquiring a greater specific gravity. It is these portions of the wood that constitute the drug in question, which is esteemed the more in proportion as it is ponderous and abounds in resinous matter. In Silhet, the collection of aloes wood is a precarious and tedious business; those engaged in it proceed some days' journey into the hilly districts, where they fell any trees they may find, young or old, and then, on the spot, search them for the aggrur, as the valued wood is called. This is done by chopping off the bark and into the wood, until they observe dark-coloured veins, indicating the proximity of wood of valuable quality, which generally extends but a short distance from the centre of a trunk or branch. In this manner a whole tree is searched through, the collectors carrying away only such pieces as are rich in odoriferous resinous matter. In some districts it is customary to facilitate the extraction of the resinous wood by burying portions of the tree in moist ground, or by allowing the entire tree to remain a length of time after it is cut down, the effect of which is to cause decay in the non-resinous wood, and thus render it easily removable by an iron instrument. I have specimens of aloes wood in which this process has evidently been adopted. Aloes wood is sorted by the collectors into various qualities, the finest of which, called Ghurkee, is worth in Silhet from 12s. to 16s. per pound. As may readily be imagined, the drug occurs in pieces of extremely irregular shape and size; I have seen none exceeding a pound in weight, while some of excellent quality is met with as small chips and splinters. The larger pieces have mostly been scooped and trimmed with great care, so as to remove, as far as possible, all the less resinous portions. The wood is of a deep brown colour, marked more or less distinctly with innumerable coarse parallel veins loaded with resinous matter. A good sample yielded me 48 per cent. of matter soluble in rectified spirit. The wood has a slightly bitter, aromatic taste; its odour is peculiar and not remarkably agreeable; some persons compare it to sandal wood, others to ambergris. In the Bible we find it associated with other perfumes, as in the Psalms† and Proverbs‡ with cassia or cinnamon, and myrrh, in the Canticles§ with spikenard, saffron, calamus, cinnamon, frankincense, and myrrh, and again with myrrh in the New Testament,∥ where it appears such a mixture was used in embalming the body of our Blessed Lord.

In the present day, aloes wood is chiefly used in China, where it is principally consumed as incense. It is, however, to be met with in all Eastern bazaars, including those of Syria, where I have myself seen it for sale. In Silhet it seems to be chiefly collected for the sake of extracting from it a sort of essential oil or oleo-resin, which is obtained, according to one account, by distillation, according to another, by infusing fragments of the wood in boiling water, and collecting

† Psalm xiv., v. 8.
‡ Prov., chap. vii., v. 17.
∥ John, chap. xix., v. 39.
the "uttur" (oil) that rises to the surface. I have a sample of this uttur which has been prepared, as I judge, by the former process.

Aloes wood has long had a place in the Materia Medica of the Pharmacopoeias of Europe, but the finer qualities of the drug have hardly ever been imported. It does not appear to possess any properties that call for its admission to modern medical practice.

牙香 Ya-heang; Wood of ? Aquilaria Chinensis Spreng. (Aquilarineae); A light, spongy wood formed of coarse parallel fibres, devoid of aroma, but having a bitterish taste. I have referred it, upon the authority of Mr. S. Wells Williams,* to Aquilaria Chinensis Spreng. (Ophismum Sinense Lour.), but with doubt, since the Chinese name given by Loureiro for that tree is Pā mŏu yong.

* English and Chinese Vocab., p. 103.
NOTES ON CHINESE MATERIA MEDICA.

BY DANIEL HANBURY, F.L.S.

厚朴 How-piā; Bark of Magnolia hypoleuca S. et Z. (Magnoliaceae); Hei-pô, Cleyer, Med. Simp., No. 200; Tatarinov, Catal. Med. Sinens., p. 8; Pun-tsaoù, fig. 735.

A rough, thick bark, which in my specimen has been tightly rolled round several times, so as form a cylinder 7 inches long by 2½ in diameter. The bark has a bitterish, pungent, aromatic taste, and is prized by the Chinese on account of its reputed tonic and invigorating properties.

黃柏 Hwang-piā; Bark of Pterocarpus flavus Lour. (Leguminosae); Tatarinov, Catal. Med. Sinens., p. 9.

Stated by Loureiro to be resolvent and vulnerary; also to be used as a yellow dye for silk.

鬱楊花 Naou-yang-kwa; Flowers of Rhododendron! (Ericaceae); Cleyer, Med. Simp., No. 186.

Used in conjunction with aconite root as a topical application to produce insensibility to the pain of a surgical operation (vide p. 31). Dr. Horaninow refers this Chinese name to Hyoscymamus.

石韋 Shih-wei; Fronds of Niphobolus Lingua Spr., Acerostichum Lingua Thumb. Flor. Jap., tab. 33 (Filices); Pun-tsaoù, fig. 414.

五倍子 Woo-pei-tsze; Galls of Rhus semi-alata Murr. (Anacardiaceae); U poi chù, Cleyer, Med. Simp., No. 225; Pun-tsaoù, fig. 839.

These galls now constitute so regular an article of commerce that it is not needful here to describe them. Some pharmacologists have asserted that Distylium racemosum S. et Z., a large tree of the nat. ord. Hamamelidaceae, growing in Japan, is the plant upon which they are produced. That this is erroneous, I have satisfied myself,—1. By an examination of herbarium specimens of this plant, and of Rhus semi-alata Murr. 2. By an examination of original packages of the galls, imported from China and Japan, which I find to contain the leaf-stalks and remains of flowers of Rhus, but never anything which I could trace to Distylium. 3. By the completely different form of the galls of the Distylium, as figured by Siebold and Zuccarini in their ‘Flora Japanica,’ tab. 94.

Chinese galls (so-called) have lately been imported from Japan; they are somewhat smaller than those shipped from China, but appear to be produced by the same tree.

沒石子 Müh-shih-tsze; Galls of Quercus sp. (Amentaceae); Pun-tsaoù, fig. 756.

These do not differ from the galls of Quercus infectoria Oliv., the common Aleppo galls of Europe.

茯苓 Füh-ling; Pachyma Cocos Fries (Fungi); Lycopodion solidum Gronovius; Pê fô tzm, Cleyer, Med. Simp., No. 189; Tatarinov, Cat. Med. Sinens., pp. 2-23; Pun-tsaoù, fig 822; Indian Bread, or Tuckahoe.

A very remarkable substance resembling large, ponderous, rounded tubers,
having a rough, blackish-brown, bark-like exterior, and consisting internally of a compact mass of considerable hardness, varying in colour from cinnamon-brown to pure white. These tuberiform bodies which in weight vary from a few ounces up to several pounds, are found attached to the roots of fir-trees, or sometimes buried in the ground in localities where firs no longer grow. They occur in South Carolina, in some of the northern and western provinces of China, and in Japan. Their true nature is sufficiently perplexing. The older writers, as Martinius and Cleyer, considered them to be a sort of China Root (Smilax), a supposition which their outward appearance certainly favours, but which is immediately negatived when we find them to contain no trace of starch. Loureiro and Endlich are content to describe them as tubers found upon the roots of fir-trees. Other botanists have placed them among Fungi; Gronovius and Walter in the genus Lycopodion, Schweinitz in Sclerotium, Oken, Horaninow, and Fries in Pachyma. The latest observations on the subject are some which were submitted to the Linnean Society by Mr. F. Currey and myself last year, and published in the 'Linnean Transactions.'* The opinion there expressed is that these tuber-like bodies are an altered state of the root of the tree, probably occasioned by the presence of a fungus, the mycelium of which traverses, disintegrates, or even obliterates, the wood and bark. This mycelium appears under the microscope in the form of fine threads, usually more or less mixed with bodies of irregular shape, some what resembling starch-granules, but which are, apparently, cells of the woody tissue in a more or less advanced state of disease and distortion. Nothing is known of the more developed form of the fungus represented by this mycelium.

The American Füh-ling has been examined chemically by Professor Ellett, of South Carolina College, who has stated it to consist entirely of pure pectin of Braconnot;† but I think its composition deserves some further investigation. I find that the pure-white internal substance (which is quite insipid and inodorous) is very slightly soluble in cold rectified spirit and in cold water, and not more so when boiled in water, the solution in each case yielding a flocculent precipitate with acetate of lead. When boiled in a weak solution of carbonate of soda, the substance dissolves rather more freely, and the solution affords a scantly gelatinous precipitate (pectic acid?) when treated with an acid, or (pectate of lime?) with a solution of lime.

In China the Füh-ling is made into edible cakes, which are frequently sold in the streets; it is also reputed medicinal in a variety of disorders. In America it has also been used as an article of food, whence the name Indian Bread.

Choo-ling; Berkeley, Journal of Proceedings of Linnean Society, vol. iii. 1859, Botany, p. 102; Currey and Hanbury, Linn. Trans., vol. xxiii. p. 95, tab. 0, fig. 10–13; Chü lim, Cleyer, Med. Simp., No. 207; Tatarinov, Cat. Med. Sinens., p. 17; Pun-taoou, fig. 824.

Tuberiform bodies of much smaller size, less regular shape, as well as less ponderous than the preceding; they are covered with a thin, black, more or less shrivelled cuticle, which closely invests a homogeneous, corky, yellowish-brown substance. The microscopic structure of these quasi-tubers resembles that of the Füh-ling; but the threads by which their substance is traversed are more interwoven and more branched, and have not the appearance of

* Vol. xxiii. p. 94, where the reader will find full references to the botanical works here referred to, as well as figures of Pachyma Cocos Fries. See also Berkeley On some Tuberiform productions from China, Journ. of Proceedings of Linn. Soc. vol. iii., Botany, p. 102, where there is a translation from the Chinese regarding these substances.
† Berkeley, l.c. p. 106.
being the mycelium of a fungus. The same irregularly shaped bodies as seen in Fū-kīn-ling, are also present, but their dimensions are smaller. In a few specimens, an abundance of doubly prismatic crystals has been noticed. "Treated with the same chemical tests as the Fū-kīn-ling," remarks Mr. Berkeley, "it [the Choo-kīn-ling] exhibits precisely the same reaction. There is not the slightest trace of starch or cellulose, and it is evident that the structure is not accordant with that of any fungus or phænogamous tuber."

The Choo-kīn-ling is stated by Chinese authors to be parasitic on a tree, beneath which it is picked up in spring and autumn. Many fanciful virtues not worth repeating are attributed to it.

雷丸 Lui-wan; Mylitta lapidescens Horaninow (Fungi); Tatarinov, Catal. Med. Sinens., p. 34; Currey and Hanbury, Linn. Trans. vol. xxiii. p. 96, tab. 9, fig. 14-17; Lū-i uin, Cleyer, Med. Simp., No. 227; Pun-tsou, fig. 825.

This substance occurs in the form of small rounded nodules, varying in weight from five grains to nearly half-an-ounce. Their exterior surface is of a dark brownish-grey colour, and generally finely corrugated: their inner substance has a granular appearance, is of a pinkish-brown colour, and of almost stony hardness. A microscopic section shows that the tissue is divided into acrolo after the manner of that of the truffle and other underground fungi; no trace of fructification has been observed in any specimen.

This curious vegetable production, which had previously only been known from its occurrence in the drug-shops of China, has lately been obtained in Southern India by Dr. E. J. Waring, who states that it is dug from the chalk-beds in the mountains separating Travancore from Tinnevelly. In India, as in China also, it is used as a medicine, being regarded as powerfully diuretic.

木安息香 Shuy-gan-seih-heang; literally, Liquid Benzoin.

This drug is a dark-brown, semi-fluid resin, having an extremely fragrant odour of storax. It is met with in small globular wooden shells, apparently the pericarp of some fruit, about 1½ inches in diameter, closed with wax. Its origin is very obscure. The Chinese assert that they import it from the Straits, or, in other words, by way of the Indian Archipelago; but I have not been able to trace it either there or in Siam. It is curious, moreover, that this fragrant resin, even to the shell enclosing it, is extremely like that kind of balsam of Peru which was brought to Europe long ago in the capsules of a Lecythis, and naturally supposed to be a product of South America.

The Liquid Benzoin is very expensive, a single shell, holding perhaps half an ounce, being worth four dollars, or 20s.

松香 Sung-heang; Sum hiam, Cleyer, Med. Simp., No. 190; Tatarinov, Catal. Med. Sinens., p. 50.—A pale-yellow terebinthinous resin, closely resembling mastich, occurring in small irregular tears, somewhat opaque externally from mutual friction, but perfectly transparent within, and exhibiting a vitreous fracture. It would be a good substitute for mastich.

The name Sung-heang is said to be also applied to other terebinthinous resins.

冰片 Ping-peen; Camphor of Dryobalanops Camphora Colebr. (Dipterocarpée); Borneo or Baros Camphor.

Obtained chiefly in Sumatra from fissures in the interior of the trunk of the tree. As the best tree when felled rarely yields more than a few ounces, the drug is very costly, being worth on the spot about 50s. per lb. It is chiefly exported to China, but a considerable quantity is consumed in the island for the purpose of embalming the bodies of the petty chiefs, a custom the expense
of which often proves exceedingly ruinous to the family of the deceased. The best quality of this camphor occurs in the form of flat colourless crystals, the largest of which rarely exceeds half an inch across. An inferior quality is coarsely pulverulent, and of a grey colour. Dryobalanops camphor has the odour of common or laurel camphor, mixed with something that has been likened to patchouli. It is less volatile than laurel camphor, and has a greater specific gravity, so that it sinks in water. Its composition is $C_{20}H_{18}O_2$, that of laurel camphor being $C_{20}H_{18}O_2$.

**Chung-pih-lah**: Chinese Insect Wax; **Pun-tsaou**, fig. 837. Secreted by *Coccus Pe-la Westw.*, upon the branches of *Fraxinus chinensis* Roxb., which is cultivated for the purpose, and possibly upon other trees. Some account of the habits of the insect by a competent observer are much required, the Chinese statements on the subject being extremely obscure.

This shell is stated to occur on the coasts of Fuh-kien and Kwantung. Messers. Cuming and Lovell Reeve, who have examined it, concur in referring it to *Haliotis funebris*, a New Holland species, figured by the latter gentleman in his beautiful 'Conchologia Iconica,' sect. *Haliotis*, pl. xii. 38.

This commodity is sold in the Chinese shops in irregular pieces of a few ounces weight, curiously covered with paper and marked with a stamp. Upon placing a thin slice of it under the microscope, its true nature is revealed, and it is proved to be fossil ivory. Many imaginary virtues are attributed to it, as well as to the following.

**Lung-che**: literally, Dragon's Teeth.—These also are fossil, and obtained, according to the Chinese, in the north-western provinces of Shen-si and Shan-si. Mr. G. R. Waterhouse, of the British Museum, who has, at my request, been good enough to examine a considerable number of specimens, is able to distinguish among them the following:—molars of the lower jaw of *Rhinoceros tichorhinus* Cuv.; fragment of tooth of *Mastodon*; of *Elephas*, near *E. insignis* F. et C.; many molars of *Equus*, teeth of *Hippotherium*, comprising molars of both jaws, agreeing perfectly with those of the *Hippotherium* of Germany and France; an upper molar of an *Hippotherium* probably distinct from the preceding; portion of an upper jaw, with the four posterior molars, of a ruminant allied to the sheep, but of smaller size; molar teeth of two species of stag; molar tooth of bear.

**Shih-heae**: Fossil Crabs of the Post-Tertiary Period. **Pun-tsaou**, fig. 66.

A celebrated Chinese medicine mentioned by Kircher, Grosier, Du Halde,
Fig. 17. The Wax-tree (*Fraxinus chinensis* Boxb.); Wax-Insect (*Coccus Pe-la Westw.*); and branch incrusted with the wax.
Clever and others, and supposed to be an antidote to all kinds of poison, as well as to possess innumerable other virtues. The specimens which I have received and which are said to be obtained in the island of Hainan and on the opposite shores of Kwang-si, belong to a single species, *Macrophthalmus Latreillii* Edw. (Gonoplax Latreilli Desm.), with the exception of one which is referable to a species of the genus *Cancer* not yet described. Probably identical with *M. Latreillii* is the fossil *M. Desmarestii*, described and figured by M. Lucas in the "Annales de la Société Entomologique de France." Nor is the animal found merely in the fossil state, for, as pointed out to me by Mr. H. Woodward of the British Museum, who has examined the subject with care, a recent species found in the Philippines and named by Mr. Adam White *M. serratus*,† appears to possess no character that can distinguish it from the fossil form.

My friend M. Rondot of Paris obtained from the Chinese pharmaciens at Canton, in addition to specimens of the *Macrophthalmus*, a fine example of *Portunus (Lupa) leucodon* Desm., recently shown by Dr. Alphonse Milne-Edwards‡ to be identical with the *Scylla serrata* of De Haan§ still found living in Japan, the Philippines and at Port Natal. It is a much larger crab than the others, measuring seven to eight inches across the carapace. There are several very perfect specimens of it, reputed to be from the Philippines, in the geological collection of the British Museum.

石 燮 *Shih-yen*; Fossil Shells; Tatarinov, *Cat. Mod. Sinens.*, p. 54; *Pun-tsaoou*, fig. 65.

These fossils have been examined and described by Mr. Thomas Davidson, to whose account and figures in the 'Proceedings of the Geological Society,' (June 13, 1853), I refer the reader who wishes for full details. The actual specimens are in the British Museum. Mr. Davidson remarks that the specimens belong to eight Devonian species, seven of which are common to several European localities, among which may be mentioned Ferques and Néhou (France), Belgium and the Eifel, but they are not found all existing together in any one of these localities. In external aspect the Chinese specimens most resemble those from Ferques, where, however, two of them, *Cyrta Murchisoniana* and *Rhynchonella Handuri*, have not yet been discovered. If to these be added two described by M. de Koninck, the total number of Chinese Devonian types at present known will amount to ten species, viz.:—3 of *Spirifer*, 2 of *Rhynchonella*, 1 *Productus*, 1 *Crania*, 1 *Cornulites*, 1 *Spirorbis*, and 1 *Aulopora*.

These fossils are asserted to occur in the southern province of Kwang-si, where coal is also met with.
